
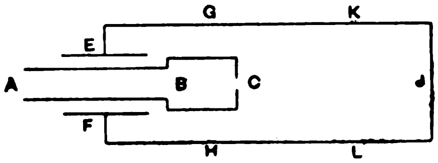

Fig. 1.

at G, J and H. By placing bits of glass tubing on the wire the sound was much intensified at the points K and L, and the phenomena made more striking. It might be supposed that by decreasing the capacity of the primary condenser, and therefore the period of its oscillation, the secondary circuit could be broken up into a new set of shorter stationary waves, with nodes at J and at points somewhere near K, L, G and H, and ventral segments between them. This we tried with perfect success, except that it was not possible to cause the light at K and L to actually disappear. There was decidedly less light at these points, however, than on either side of them. The light, of course, is simply that which always appears around wires carrying very high potential currents, the interesting point being that it appears in some places on the circuit and not in others. The experiment showing how the circuit breaks up in several different ways would form a most beautiful lecture experiment.

As a means of ascertaining when the circuits were in resonance, and of investigating the form of the wave in the secondary circuit, a bolometer similar to that designed by Paalzow and Rubens* was used.

The bolometer as an instrument for measuring electric waves is so well known, that it is not necessary to state here more than its fundamental principles. It consists essentially of a well-balanced Wheatstone bridge, to one of the arms of which are metallically connected two small conductors. These conductors are brought near the circuit to be tested, and the oscillating charges induced in them and sent through the arm of the Wheatstone bridge develop enough heat to throw the bridge out of balance. By moving the conductors along the circuit different deflections are produced according to the magnitude of the charges on the wire in their neighbourhood, and thus an excellent estimate of the wave formation can be obtained. In the present case the conductors that were brought near the secondary circuit consisted of two pieces of wire insulated with rubber, bent into circles of about 2cm. radius, and fastened to a bit of pine-wood by means of a heavy coating of paraffin. The two wires of the secondary circuit

passed through holes in this bit of wood in such a manner as to pass through the centres of the two circles. In the early part of the investigation the bolometer and galvanoscope were placed at a sufficient distance from the oscillating circuits to prevent any direct action of one on the other, and the leads running from the circular conductors to the bolometer consisted of long fine wires. Later, when longer circuits and longer waves were experimented with, great inconvenience was experienced from the long leads, since their relative position had considerable effect upon the galvanoscope deflections. In order to obviate this difficulty short leads of heavily insulated wire were used, and the bolometer was placed on wheels and moved along from place to place. A bolometric study of the circuit just described showed the character of the oscillation to be that mentioned, namely, nodes at the points J and G H, and a ventral segment at K L. A careful run was made from one end of the circuit to the other, which furnished data from which a very regular curve was drawn.

The insertion of a small spark-gap (1mm. to 3mm.) at the point in the secondary circuit marked J (Fig. 1) had no appreciable effect upon the position of the nodal point G H, or of the point of maximum accumulation K L. The form of the wave was slightly altered for a metre on each side of J, and the bolometer showed a slight accumulation in the immediate neighbourhood of the spark-gap. This was probably due to the charging of the spark terminals to a sufficiently high potential to break through the dielectric. The fact that the insertion of a spark-gap into a secondary circuit in the manner described has no effect upon the length of the waves set up in that circuit was tested for a number of different cases (in none of which, however, was the length of the waves greater than in the present case), and found to be true in each one of them.

In order to determine the time of vibration, we used a concave rotating mirror, and the images of the oscillating sparks were thrown on a sensitive plate. If the mirror rotated about a horizontal axis the photographs showed bright horizontal lines, perpendicular to which at their extremities extended two series of dots. The distance between successive dots was the distance on the plate through which the image of the spark-gap moved during the time of a complete oscillation. Hence, by determining the speed of the mirror, and measuring the distances from the mirror to the plate, the time of oscillation could be calculated. To measure the sparks we used a sharp pointer moved at the end of a micrometer screw under a magnifying glass of low power. The instrument was originally intended for microscopic measurements, and was very accurately constructed. The rotating mirror was driven by an electric motor by means of a current from a storage battery of extremely constant voltage. To give great steadiness a heavy fly-wheel was attached to the axis of the mirror. The speed of the mirror was determined to within about one part in 500 by means of an electric chronograph. This apparatus, requiring great technical skill, was made for us by the mechanician of the laboratory. The mirror consisted of a thick piece of glass with a concave surface accurately ground for this research by the well-known optician Alvan Clark, and silvered by ourselves. For the extremely sensitive dry plates which were used we are indebted to Mr. Gustav Cramer, of St. Louis, Mo.

There are many advantages in photographing the secondary spark rather than the primary. In the first place, to properly photograph a spark it is necessary to use pointed terminals; but experiment has shown that the waves excited in a secondary circuit depend to a large extent upon the character of the primary spark, and that the most active sparks are those between metallic spheres with polished surfaces. It is true that waves can be produced by sparks between points, but the oscillations are not so powerful or well marked. In the second place, from the results obtained by Bjerknes one would expect the oscillations in the secondary circuit to be much less damped than those in the primary. This expectation has been fully realised. Photographs show from ten to twelve times as many oscillations in the secondary as in the primary. The longest secondary spark we counted indicated 60 complete oscillations. In the third, and by no means the least important case, the question how close the resonance is does not affect the accuracy of the results. By photographing the sparks in the secondary the period of oscillation is determined, not of a circuit that is altered until by trial it is found to have as nearly as possible the same period of vibration as the circuit on which the length of the wave is measured, but that of the circuit along which the wave itself is actually travelling; and hence the conclusions in regard to the effect of damping reached by Bjerknes in his admirable Paper on "Electric Resonance"* do not affect the accuracy of the results.

The great difficulty to be overcome is the production of secondary oscillations that will produce sparks sufficiently bright to photograph. It is comparatively an easy task to photograph the primary spark, but in order to photograph the secondary the dimensions of the circuit must be chosen with great care.

With a view to increasing the light of the spark, together with the length of the waves, it seemed desirable to lengthen the period of oscillation by enlarging the condensers rather than by increasing the self-induction of the primary circuit. A castor-oil condenser, therefore, was designed and constructed on the following plan:—Eight plates (25cm. by 20cm.) were cut out of sheet zinc, and were held in vertical planes side by side 2cm. apart by a suitable hard-rubber frame. The plates were entirely immersed in castor-oil contained in a glass jar. They were connected together in the manner shown in Fig. 2. The plates marked *a*, *c* and *e* were fastened to the conductor A B, and formed one armature of the condenser. Those marked *d*, *f* and *h* were joined to C D, and formed the other armature. The two ends of the secondary circuit E, G, J, H, F were fastened to the plates *b* and *g*. The plane of the secondary circuit was 50cm., and that of the primary 3cm. above the upper edge of the condenser plate. The total length of the secondary circuit from one condenser plate through E, G, J, H, F to the other plate was 6,338cm. The circuit consisted of copper wire (diameter 0 215cm.) supported at each end by suitable wooden frames, and also once in the middle by hard-rubber hooks, fastened by long pieces of twine to a wooden crossbar above. The distances from F to E and from K to L were 30cm., and a spark-gap with pointed tin terminals was inserted at J. The primary circuit consisted of copper wire (diameter 0·34cm.). The distances between the two parts A B and C D were 45cm. The portion B D contained a spark-gap with platinum-faced spherical terminals, and was made so as to slide back and forth, to and from the condenser. The motion of this movable piece varied the self-induction, and therefore the period of oscillation of the primary circuit. By this means the circuits were brought into resonance. With certain arrangements of the condensers the resonance was very sharp, and the position of the movable portion could be determined to within 0·25cm. In the arrangement which was finally adopted, the resonance was not so sharp. Even in this case the distance of the sliding part from plate *a* could not have been in error by more than 2cm. The length 65cm. was finally chosen for its value.

The automatic current interrupter that worked so beautifully in connection with the Hertz vibrator would not function well when used to excite the circuits just described. After trying many

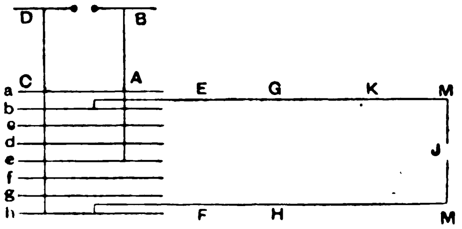

FIG. 2.

devices, we finally adopted an ordinary reed interrupter with a comparatively large hammer-and-anvil arrangement, which gave little trouble.

At first it was found impossible to produce anything but a complex vibration in the secondary circuit when the spark-gap was open. Some slight evidence of resonance was obtained, but nothing of a decided character. When, however, the spark-gap was closed, very good resonance ensued, and a wave the length of which could be measured to within 0 4 per cent. was excited. Some photographs were taken of the spark in the secondary circuit, and they showed immediately the character of the complex wave formation. The secondary circuit could and did oscillate in three different ways, and the ratios of the periods were those of the notes in an open organ-pipe, namely 1:2:3. Usually the lowest or fundamental oscillation together with one of the overtones was present; but several sparks were noticed that furnished unmistakable evidence of the simultaneous existence of all three. We have observed in a circuit 10,000cm. long the same peculiarities of oscillation, excited by a primary circuit that, judging from its dimensions, could not have been in resonance with the secondary. It was evident that the oscillation having a node between the points marked E and F (Fig. 2) is that whose period is one-third of the fundamental.

A number of measurements of this period have been made, and from these values the velocity of the waves has been calculated. The results appear in the table on next page. As an average of five measurements of the wave length, none of which differed from the mean by more than 20cm., the value 5,888cm. was chosen. The distance from the mirror to the photographic plate in each case except the last was 300·1cm. Each of the first five values in the second column of the table is an average of 30 measurements of distances ranging in the neighbourhood of 1cm.

The last line in the table contains the results of measurements on photographs of the primary spark instead of the secondary. In this case the distance from the mirror to the photographic plate was 311·5cm.

These results we published as a preliminary record in the *American Journal of Science* for April, 1895. At that time we did not think, judging from the table as it stood, and from a consideration of the possible errors in the various measurements, that the total error in our determination could have been as great as the difference between the average just quoted and $2{\cdot}998 \times 10^{10}$, which is generally accepted as the velocity of light. Since then we have succeeded in producing much better waves and much more regular sparks, and have discovered a phenomenon which renders a measurement on a photograph over a space where the dots are obliterated a questionable proceeding. The new data have given a value for the velocity more in accord with theory.

Number of revolutions of mirror per second.	Distance between two successive points on plate. Centimetres.	Velocity of waves. Centimetres.
71·2	0·05608	$2{\cdot}819 \times 10^{10}$
70·85	0·05600	$2{\cdot}810 \times 10^{10}$
70·7	0·05532	$2{\cdot}835 \times 10^{10}$
71·3	0 05637	$2{\cdot}808 \times 10^{10}$
70·8	0·05611	$2{\cdot}808 \times 10^{10}$
	Average......	$2{\cdot}816 \times 10^{10}$
69·2	0·05340	$2{\cdot}988 \times 10^{10}$

Since the waves in the secondary were not well formed when the spark-gap was inserted, it seemed desirable to try to find an arrangement that would produce simultaneously a good wave and a photographable spark. A number of condensers with plates of different sizes and shapes and different substances for the dielectric were tried, and the apparatus to be described was finally adopted. The difficulties to be overcome were these. Too strong a reaction between the primary and secondary condensers could not be employed, because the increase in the damping of the primary due to the large amount of energy drawn off by the secondary made good resonance impossible. The amount of energy in the primary at full charge must be much greater than that in the secondary. On the other hand, the capacity of the primary condenser must not be too great; for the self-induction of the primary circuit would have to be proportionately small, and this, too, means an increase in the damping. The secondary condenser, too, must have a capacity of less than a certain magnitude in order that the node may fall on the circuit and not in the condenser plate. These points seem to indicate that small condensers are preferable to large ones; but a decrease in the size of the plates means a decrease in the light of the secondary sparks, and the sparks are at best barely photographable. Practically, therefore, our choice was much limited, and the particular arrangement to give the best results had to be selected by experiment after a long series of trials. The arrangement and dimensions of the apparatus finally adopted were as follows :—

Two metallic plates, *a* and *b* (Fig. 3), 30 × 30cm., placed in vertical planes, formed the primary condenser. The dielectric between them consisted of the best French plate glass obtainable (K=8+ probably) and was 2cm. thick. Outside the plates *a* and *b*, and separated from them by a hard-rubber dielectric (K=2+about) 1·8cm. thick, were the secondary plates, 26 × 26cm. The primary and secondary circuits were joined to the condenser plates as indicated in the figure. The primary circuit lay in the horizontal plane passing through the centres of condenser plates, and consisted of copper wires 0·34cm. in diameter. In order to control the period of oscillation of the primary circuit, the portion B D containing a spark-gap with spherical terminals was made, as before, so as to slide along parallel to itself. The distance between the straight portions A B and C D was 40cm., and the lengths of A B and C D finally chosen for best resonance were 85cm. Most of the secondary circuit lay in a horizontal plane 16cm. above that of the primary. The lengths G E and H F, however, were bent down and fastened to the middle points G and H of the secondary plates. The circuit consisted of copper wire (diameter 0·215cm.), and its total length from G through J to H was 5,860cm. At J was a spark-gap with pointed terminals. With this apparatus we succeeded in producing a very regular wave formation, as indicated by the bolometer, even when there was a spark-gap at J. So many curves have been plotted and published to illustrate the characteristics of electrical waves that it does not seem worth while to add to the number here. It will be sufficient to state that the ratio of the maximum and minimum deflections in the bolometer was about 15 : 1, and that there was a node at J, and another about 40cm. to the right of E and F.

Upon photographing the secondary spark some curious phenomena were observed. In the first place, the dots usually appeared in pairs. There would be two black dots followed by a space where two or three dots either appeared faintly or were absent altogether; after that two black dots would reappear, followed again by a faint space, and so on for six or seven repetitions. All this, of course, occurred in a single spark.

The explanation that first presents itself is that the two black dots are the result of the first two oscillations in the primary circuit, which, owing to the damping, are much more powerful than the others. If this were the true reason, the first of the pair of dots always ought to be blacker than the second, and every third dot ought to be the first of a pair. This is not the case, however. On the other hand, the phenomena cannot be explained as the result of a complex vibration, for the bolometer readings, taken only a few minutes before the photographic plates were exposed and with exactly the same arrangement of apparatus, indicated extremely regular waves. A clue to the mystery was furnished by several sparks in which the dots made by one spark terminal had the characteristics just described, whereas those made by the other were quite regular. Following out this hint, we found that the particular substances used for the secondary spark terminals had a large effect upon the characteristics of the photographs. We tried spark terminals made of a number of different metals—tin, aluminium, magnesium, fuse-metal, &c.—and finally adopted cadmium as productive of the best sparks. In the case of cadmium the characteristics described are much less marked, and we have succeeded even in producing a few sparks in which no difference in blackness could be detected between one dot and the next. The photographs from cadmium terminals, too, are far more distinct and far more easily measured than those from terminals of any other metal that we tried.

An interesting question arose here as to whether the distance between two successive dots would depend upon the period of oscillation of the primary circuit if the secondary were unaltered. To test this point the circuits were brought into resonance, and a photograph taken. The self-induction of the primary circuit was increased by about 20 per cent. of its value, and a second photograph taken. In the first case the distances between successive dots were all within 2 or 3 per cent. of the average obtained by measuring over several dots and dividing by the number of intervening spaces; whereas in the second case the measurements of some of the single spaces were from 8 to 12 per cent. greater than before, the average from long measurements being the same. This indicates that the vibrations of the secondary circuit are not necessarily perfectly regular, and at a distance apart fixed by the character of the circuit, but are to be looked upon as a series of

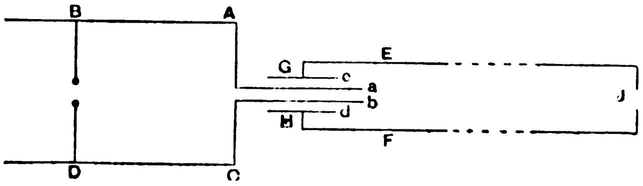

Fig. 3.

pulses started travelling along the circuit and keeping at a distance from each other that is determined by the exciter. Owing to the fact that the damping of the primary is much greater than that of the secondary, the seventh and eighth pulses started are too weak to obliterate the first and second, which have travelled the length of the circuit and back. We should expect from this that the bolometer throws, which measure the average length of the wave, would not indicate a shifting of the node when the circuits are thrown slightly out of resonance, but that the minimum throws would be greater than when the circuits are exactly in resonance. This, as is well known, is what happens.

The improved sparks which the new arrangement of apparatus and the use of cadmium as material for the spark terminals have enabled us to produce, have brought to light another interesting fact, namely, that even when the best resonance is obtained and the most regular wave formation is excited, the distances between the first three or four dots are slightly greater than the distances between three or four dots taken farther down the spark. The explanation we offer for this is the following, and it applies as a criticism to all cases in which waves are excited in a circuit by a neighbouring circuit possessing a much larger damping factor. The fact that the secondary waves last longer than the primary oscillations means that the last times that the waves travel over the circuit they do so under different end conditions from the first few times. The capacity of the secondary plates is slightly less after the primary spark has stopped than it was before, and therefore the length of the wires equivalent to the secondary plates is slightly less, and it takes a shorter time for the waves to travel along the circuit and back. Hence the observed decrease in the distance between the spark points and a certain mixing up of the dots, which occurs after the sixth or seventh oscillation (see Fig. 2). The sixth dot in the figure, apparently following its predecessor after about half an interval, is not a usual characteristic. In the vast majority of sparks the first few dots are far more powerful than those that follow them, and only occasionally

Digitized by Google

do sparks occur that indicate more than five or six good complete oscillations. Hence these first few oscillations have the preponderating influence in fixing the length of the waves as indicated by the bolometer. In examining the sparks, therefore, we measured from the first oscillation as far down the spark as we could without passing over a space where dots were obliterated; and hence in every case we knew the number of dots between the points from which measurements were taken, and did not have to assume that good oscillations had occurred without affecting the plate.

The following table, containing the results of our measurements with the improved apparatus, explains itself. The distance from the mirror to the photographic plate was 302cm. in each case:—

Number of revolutions of mirror per sec.	Distance between successive points on plate. Centimetre.	Time of oscillation. Seconds.	Length of wave. Centim.	Velocity of wave. Centim. per sec.
70·8	0·05028	$1{\cdot}871 \times 10^{7}$	5,670	$3{\cdot}030 \times 10^{10}$
73·7	0·05247	$1{\cdot}876 \times 10^{7}$	5,670	$3{\cdot}022 \times 10^{10}$
75·2	0·05536	$1{\cdot}940 \times 10^{7}$	5,670	$2{\cdot}923 \times 10^{10}$
69·5	0·05002	$1{\cdot}897 \times 10^{7}$	5,690	$3{\cdot}000 \times 10^{10}$
68·9	0·04900	$1{\cdot}874 \times 10^{7}$	5,690	$3{\cdot}036 \times 10^{10}$
69·0	0·04974	$1{\cdot}899 \times 10^{7}$	5,690	$2{\cdot}996 \times 10^{10}$
71·2	0·05075	$1{\cdot}878 \times 10^{7}$	5,660	$3{\cdot}014 \times 10^{10}$
Average Value of Velocity..................				$3{\cdot}003 \times 10^{10}$

With the exception of three preliminary trials, which gave values differing from the mean by 10 per cent. or by 12 per cent., these are the only determinations we have made. In some cases the waves in the circuit were just as good with the spark-gap as without it. In others there was a decided wave formation when sparks occurred, but the node was not quite so well marked. For this reason, and since it did not appear to make any difference in their length, the waves usually were measured without the spark-gap. As the sparks were quite regular, the difference in the bolometer readings must have been due to Faraday tubes that were reflected from the spark-gap without forming a spark and reversing themselves. The variation in the number of revolutions of the mirror per second is due to the fact that different cells were used to drive the motor on different occasions.

As an example of the data taken to ascertain the position of the node we give the following table. The top line contains the distances of the bolometer terminals from a pair of arbitrary fixed points on the circuit:—

Distances from fixed points . .	20cm.	40cm.	60cm.
Bolometer deflections	4·3	4·0	4·3
	4·5	4·1	4·4
	4·5	4·0	4·2
Average deflections	4·43	4·03	4·3

From these deflections the position of the node was estimated. It appears from the best results that we have obtained, that the velocity of short electric waves travelling along two parallel wires differs from the velocity of light by less than 0·2 per cent. of its value. It has been shown theoretically, that the velocity of such waves travelling along a single wire should be the velocity of light approximately. Our results, therefore, in a certain sense confirm the theory to an accuracy within their probable error. Theoretically, too, the velocity should be approximately equal to the ratio between the two systems of electrical units. The average of the best measurements of this ratio is 3·001, which is nearer the average velocity obtained by us than the velocity of light.

ELECTRIC CABLE APPARATUS.

We illustrate this week two handy machines by Messrs. John Davis & Son, of Derby, intended for wire manufacturers, contractors and others. Fig. 1 shows a machine for measuring wires and cables from 40g. to 1in. diameter. It consists of a strong but light steel wheel, mounted on a steel spindle in a cast-iron frame, and having a fine worm cut on the spindle geared into a worm wheel and driving a train of clockwork connecting the hands of the dials which indicate units, tens and thousands of feet or yards, or metres, &c., according to requirements. To prevent error due to slipping, or similar causes, it will be noticed that there is a small roller on the top of the wheel upon which the wire or cable to be measured runs. This roller presses the wire or cable on to the wheel. The shaft of the roller projects through the frame, and on this shaft sufficient weights are fixed. In the case of very small wires it is best to lap the wire once round the measuring wheel. In the case of less flexible cables their own weight and the small roller is sufficient to prevent any slip. The machine should prove a great convenience to manufacturers and contractors, as by means of it cables and wires can be automatically measured during or after process of manufacture, and before being sent out to a job and returned

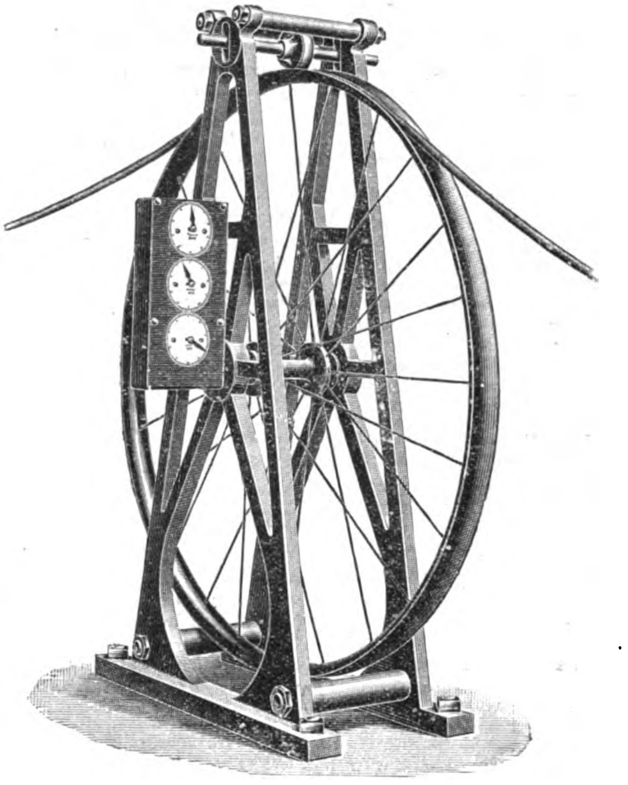

Fig. 1.—Cable-measuring Machine.

lengths before being put into stock. Adjustable contacts are also fitted to the dials to ring a bell when any desirable length has passed.

Fig. 2 indicates a light cable drum mounted on a steel spindle in a cast-iron frame, which is found to be a useful and simple time-

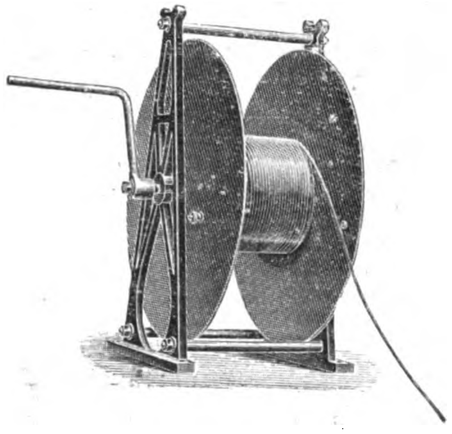

Fig. 2.—Wire Drum.

saver for putting wires and cables into neat coils before being sent out. It is also very useful in telling out cables and wires in installation work. If used for coiling cables, one side takes off, and the drum is made slightly taper so as to allow the cable to slip off.

The Willans Engine in France.—The recently-formed Company known as the Société Industrielle des Moteurs Electriques et à Vapeur, which has taken over the Heilmann electric locomotive patents, has also acquired the exclusive rights in the Willans engine in France and the French colonies. The French-made Willans engines will be constructed at Havre, in the works of the Company.

ELECTRICAL MANUFACTURING IN ENGLAND.

The annual reports of the Directors and the meetings of the shareholders of the three electrical manufacturing companies whose capital is held to any considerable extent by the public are now matters of history, and have been duly chronicled in our columns. We refer to those of the Brush Electrical Engineering Company, Crompton and Co., and the Electrical Construction Company. It must be admitted that if these reports reflect accurately the general commercial results of electrical engineering and manufacturing the outlook is far from rosy. In the first case, an interim dividend amounting to 2½ per cent. for the year was paid on the Ordinary shares, but it was declared owing to a sanguine view having been taken of the prospects of the Company, a view which unfortunately was not realised; whilst a dividend at the rate of nearly 4½ per cent. was earned, and was payable to the Preference shareholders. In the second case no dividend was paid on either the Ordinary or Preferred shares. In the third case a dividend at the rate of 7 per cent. was paid on the Preferred shares, the amount being trifling, and none on the Ordinary, though it is fair to state that an amount was added to the balance of revenue account, which would have paid 2¾ per cent. on the Ordinary capital. Owing, however, to the large debenture and loan capitals with which all these companies are working, the payments on the share capitals give no criterion of the earning capacity of any of the businesses. The only way to make any comparison is to take the total capital used in each business, comprising paid-up share capitals, debenture capitals, loan capitals, adding trade creditors (this last item being in some cases a means of providing working capital), and to set against these the total earnings in the year, which have or might have been properly paid to the owners of the capital. Reviewing in this light the three businesses concerned, we arrive at the following figures: The Brush Company, on a total capital sum of £697,888, earned 2·2 per cent.; Crompton and Co., on £291,174, earned 2·38 per cent.; the Electric Construction Company, on £551,366, earned 4·6 per cent.

Digitized by Google

The Chairman of the meeting in each case had an explanation to offer as to why better results had not accrued. The Brush Company had lost over a dispute arising out of the City of London contract; Crompton and Co. were very slack for six months; the Electric Construction, by implication, had taken contracts at too low a figure, but having plenty of work in hand, were raising prices. But the fact remains that all these are contingencies, which may and must occur in turn to all such concerns, and the average profits must allow for them before the results can be considered satisfactory. In the absence of any figure in the reports or balance sheets as to the actual turnover it is difficult to form an opinion whether the above unsatisfactory result arises from the rate of profit on the turnover being too small, or the proportion of capital to turnover being too large. Some of the figures given, however, throw very suggestive lights on the question. Nearly 25 per cent. of the whole assets of the Electric Construction Company consists in shares and debentures of other companies, which only produce a little over 4 per cent.—less than the average rate paid by the Company for interest on its secured loans. This proportion of its capital is therefore a dead weight on the concern. Then comes that item which, like charity, covers a multitude of former errors—"goodwill." A speaker at the Crompton meeting urged the Directors to face facts, and purge the balance sheet of such items. It is almost impossible for anyone to judge of the reality of such an asset except Directors who know the business intimately. In the case just named, for example, patents, preliminary expense accounts and goodwill form nearly 20 per cent. of the capital account. Are they of such value that the profits of the Company are 20 per cent. greater than those of a manufacturer who does not possess them? In these days of lowest tenders to specifications it is open to question. And thus we might pursue our way through the other accounts, but to little purpose. More general considerations will prove better worth following.

It must never be forgotten that notwithstanding the doubtful financial policy that has at times distinguished these businesses, they have had a difficult task to perform, and have, on the whole, acquitted themselves well; they have done pioneering work to their own credit, and to the lasting benefit of the whole electrical industry and profession, and the cause of the poor pecuniary return is not to be found in the value of particular items of their balance sheets. What is wanted to make all these concerns pay is more work, and in spite of the fact that the last year or so has seen the closing of some manufacturing concerns, there are still too many in the trade for the existing amount of business, and this tells more on the electrical trade than on any. It is a trade requiring a larger proportion of skilled supervisors than almost any other, and these cannot be reduced at every fluctuation of business; hence periods of slackness tell with unusual severity. Then there is the competition of those who combine electrical work with other engineering work, so as to decrease the weight of this disadvantage; and this point has been evidently realised by the Directors of the Brush Company, who are adding a new item in the way of a high-speed engine to their collateral industries; and in this direction we cannot help thinking all will be eventually forced, unless great strides are made in stimulating demand. Talk there is, and has been for years, of *raising* prices; but the fact is that if motors and electrical appliances are to become part of our daily life, prices must *go down*. The countershaft holds its own over the distributing motor because of its cheapness, and this reason also in numberless cases determines the scales in favour of gas-pipes instead of an electric installation. The public and engineers have been educated to understand the advantages of electric systems, but price bars the way.

Prof. George Forbes, in his recent article in *Blackwood* on "Harnessing Niagara," states that he was the first consulting engineer that the American manufacturers had had to deal with. Happy American manufacturers! The influence on cost that is exercised by consulting engineers in this country by insistence on alterations to standard patterns to meet fads can hardly be exaggerated. But competition is so keen that the manufacturers cannot make a firm stand; and this is one reason why municipal work, which might at the present time be a tower of strength to the trade, is really hardly worth touching for the profit it brings. And yet so small, apparently, is the reliance placed by public bodies on the consulting engineer, that the payments for such contracts are prolonged on the principle that the proof of the pudding is in the eating—in other words, the payments are prolonged till the working of the plant has proved that it is what is wanted.

"What are you busy with now?" was the inquiry addressed by an English engineer to the President of one of the largest American manufacturing concerns a year or so ago. "I am busy trying to keep the receiver off the doorstep," was the reply. That has unfortunately been very nearly the truth with some of our English electrical businesses. Things are a little better now; we can only hope that the energies thus liberated will be utilised in doing that which alone will bring money to the shareholders, viz., increasing the demand for electrical goods, either by overcoming the terrible prejudice in this country against the electric tramway, or by so cheapening manufacture that markets at present barred will be available. Next year's annual reports will then be more palatable reading for those to whom they are addressed.

OBITUARY.

SIGMUND SCHUCKERT.

On Monday, September 16th, Herr Sigmund Schuckert, founder of the well-known German firm of Schuckert and Co., died, after a long illness, at the early age of 49. Owing to Herr Schuckert's great modesty, the important part he played in connection with the development of electrical engineering has, perhaps, never been fully recognised. He was not only the creator of one of the earliest and largest electrical engineering establishments in the world, but he was also largely responsible for the development of the continuous-current arc lamp.

Sigmund Schuckert came of an old Nuremburg family, and was born in that town on October 18, 1846. He received his mechanical training in a workshop in his native town, and afterwards spent five years in various workshops in Stuttgart, Hanover, Berlin, and Hamburg. At this period of his life a longing to see foreign lands came upon him, and in May, 1869, he went to America. During the next four years he was employed at New York, Baltimore and Philadelphia, and made the acquaintance of Thomas Alva Edison. In the year 1873 he returned to Germany on a visit, but was persuaded to remain and start a workshop in his parent's house. Very soon, however, he moved his shop to an old mill where water power was available. He had at first only one assistant, and made instruments of precision. A new type of pedometer dates from this time. Meanwhile he paid great attention to his education in theory, and the numerous marginal annotations in the books of the Schuckert library give ample proof of his diligence.

It was at this time that he designed and constructed his first dynamo. Speaking of this machine in later days, he related how at the time of construction a well-known physicist told him that it would never work, but the machine, never-

Digitized by Google

theless, worked for 20 years, and was then bought back by Schuckert as a memento of days gone by. This dynamo and several more of the same type were used for electro-deposition. Electric lighting at that time was very little known, but Schuckert was continually working at it. In 1875 he was rewarded for his labours, and erected his first arc-lighting plant on the occasion of the Sedan *fêtes* at Nuremburg. This arc-lighting machine, of the flat-ring type, was designed with great judgment, and proved of great importance in later years, as was shown by the position it held in the technical world. At that time it was not generally known that by using laminated iron and large field-magnets, the heating of the armature could be to a certain extent avoided, and amongst the then existing machines, which had more copper in the armature than in the field-magnets, a well-ventilated and easily repairable type of armature was of the utmost importance. A great impetus was given to the Schuckert undertaking by the progress of continuous-current arc lighting. At that time the alternate-current arc lamp of Siemens and Jablochkoff almost monopolised the market and Schuckert endeavoured to construct a continuous-current lamp which should succeed equally well. He was ultimately successful, and after acquiring the patents of Krizik, brought out a lamp, known later in England as the Pilsen arc lamp. In 1883 he was employing 100 hands, and in 1886 this number had doubled itself. Schuckert improved the system of the parallel running of arc and glow lamps, and put two arcs in series across a 100-volt circuit. All these things appear now a matter of course, but at the time great opposition was experienced, and his manager, Herr Alexander Wacker, who is to-day Chief Director of the Company, bravely helped him to fight against public prejudice. The Schuckert establishment grew steadily, and in the year 1890 he was employing 1,000 men. He showed good judgment in the selection of his assistants, among whom were the well-known electricians Uppenborn and Hummel, the commercial part of the concern being left in the hands of Herr Wacker. As the business grew, new departments were taken in hand, town lighting, tramway work, and power transmission being made a speciality. To-day, in the Schuckert dynamo, arc lamp and instrument shops alone over 2,000 men are employed.

How persistent Herr Schuckert was in bringing new inventions to a practical shape is shown by the introduction of the projector with parabolic mirrors for military and naval purposes, and which later attracted so much attention all over the world. When Prof. Munker suggested the use of this pattern of projector, Herr Schuckert at once took up the idea, and although many a disappointment was experienced while the experiments were being carried out, he ultimately succeeded in producing a workable apparatus. Afterwards the Schuckert projector was tried before a military commission, and proved far superior to any then existing, and the late Dr. Werner von Siemens, who was always ready to acknowledge the merits of others, shook hands with the indefatigable experimenter, and said, "Siemens humbles himself before Schuckert."

With all his success, Sigmund Schuckert preserved a simplicity and modesty which became proverbial amongst all who knew him. He was always ready to extend a helping hand to those under him, and during his long illness he was working out a scheme for the benefit of his employees. In the death of Herr Schuckert the electrical engineering industry has sustained a severe loss, and it is lamentable that so active a mind should have been extinguished whilst still in its prime.

Electric Road Carriages in America.—A *Herald* correspondent reports that two electric carriages are being built in Camden, N.J., for the *Chicago Times-Herald* race from Chicago to Milwaukee in November. No names are given, "but some rather strong claims are made for the vehicles." They are to be equipped with a storage battery which will run the vehicle 500 miles before requiring to be recharged, at a speed of 17 miles an hour, and this "at a cost of but 13 cents for each 50 miles."

THE BRITISH ASSOCIATION AT IPSWICH.

(*Concluded from page 680.*)

Tuesday, September 17th.

An attractive Paper was read on Tuesday, in Section G, which met in the Public Hall—where the Presidential Address had been delivered—for the purpose of hearing it. This was a Paper on "The Field Telegraph in Chitral," and was read by Mr. P. V. Luke, the Deputy Director-General of Indian Telegraphs. The author commenced by describing the usual expedition equipment, as supplied by the Indian Civil Telegraph Department. All the equipment is arranged for pack carriages, in packages of not more than 80lb. each, *i.e.*, half a mule-load. The total equipment for one office, including tents, &c., comprises seven mule loads, but can on occasion be reduced to four such loads. Telephone apparatus is always carried, in addition to the sounder telegraphs. Two classes of line wire are carried: iron wire weighing 150lb. to 300lb. per mile, and stranded copper wire weighing 80lb. per mile. These are strung to such poles as the resources of the country permit of; but in barren districts, light iron poles are conveyed to the route. These latter are of tubular sheet iron, constructed to close up telescopically. In the Waziristan campaign, a single line of this form was erected at the rate of nine miles a day for five consecutive days. Special arrangements for rapid repair are always made; for this purpose it is necessary to have a telegraph office at every 10 miles, with a trained line staff. For the signalling staff trained British soldiers are mainly used; these men are employed at other times at different telegraph offices throughout the country, usually where their regiments are quartered. The Field Telegraph forms a distinct department in the field, under a civilian telegraph officer appointed by the Director-General of Telegraphs, and taking his orders from the chief of the staff. Information of the siege of Chitral came from Gilgit over the line which was only completed in 1894. This line is carried over two passes, one 11,600ft., the other 13,500ft. above sea level, where the snow lies from 10ft. to 18ft., yet it worked well all through the winter. The staff at the observation stations close to these passes are entirely cut off from the rest of the world except by wire for seven months in the year. The place selected as the base of operations was Holi Mardan; best material for a two-wire 200-mile line with 20 offices was at once collected, together with the necessary staff for constructing and working. From this point the wire was pushed on as fast as possible, and a field office was opened on the Malakand Pass a few hours after the battle. At first it was a single-wire line, but it was afterwards made a three-wire line as far as the Swat Valley, then a two-wire to Dir, and finally one wire to Chitral Fort. Great difficulties with transport occurred at Lowari Pass, owing to the Pass not being passable for camels; but for this the wire would have been into Chitral by May 12; as it was it did not reach there till midnight of the 17th. On account of the scarcity of timber it was necessary to use iron poles very extensively; at the Lowari Pass, however, there is a fine pine forest; wooden poles were afterwards used. After May, cutting the wire became very frequent, and even very difficult to stop. After the start the traffic, which was exceedingly heavy, was dealt with, with but little delay; in April 24,370, and in May 58,935 messages were dealt with, and their length was much above the average. Shortly after the Malakand fight, by clearing the line right through to Simla, the Commander-in-Chief was enabled to talk direct to Gen. Low, and in spite of heavy rains at the time the communication was excellent. To give some notion of what was accomplished, it may be stated that a telegram dated Chitral Fort, May 19th, was published in the London papers of the same date. The Telegraph Department also assisted in defending camps by running wires round the camp, so arranged that an alarm was at once given by the ringing of a bell in the Quarter Guard should a night surprise be attempted, and in many other ways much aided and assisted the military authorities

Meanwhile, in Section A, a long programme of electrical Papers was being commenced. The proceedings opened with a further description, by Lord Kelvin, of the researches on the

Digitized by Google

"Electrification and Diselectrification of Gases," which he and Messrs. Maclean and Galt have undertaken for some years past. Some account of this communication will be found in another column. In the discussion, it was suggested by Dr. Oliver Lodge that there would be considerable interest in testing the effect of bright light projected upon the polished metal surface of the electric filter. The influence of violet and ultra-violet rays on electric discharges is well defined, under certain conditions, and it might be instructive to test their influence on the diselectrification of gases.

The next Paper sought to answer the question, "Do Vertical (Earth-Air) Electrical Currents Exist in the United Kingdom?" and was read by Prof. Rücker, by whom researches on the subject have recently been undertaken. At the Oxford meeting of the British Association, last year, Dr. Adolph Schmidt gave an expression for the earth's magnetic force at a place, one term in which expression seemed to be "due to electric currents traversing the earth's surface." To test whether any such currents exist in the United Kingdom, Prof. Rücker has taken a circuital round a number of well-defined areas—dealing with each one separately—and has investigated whether the line-integral of the horizontal magnetic force in this circuital is or is not a vanishing quantity. The results of his researches go to show that there is not within the United Kingdom, under normal conditions, any vertical current of so great a magnitude as that proposed by Dr. Schmidt. There may possibly be a current one-tenth of that amount, or about 0·01 ampere per square kilometre. It was pointed out that these results do not necessarily upset Dr. Schmidt's hypothesis, as there may be such electric currents in other countries, or it is possible that they exist between the water and the bed of an ocean. In the discussion Lord Kelvin stated that he had found that no less than 36 times the normal fine-weather electrification would have to be given off from the surface of the earth by upward air currents, if this hypothetical earth-air current is to be explained on the theory of electrified air convection streams.

Mrs. Ayrton now contributed a Paper "On the Equation connecting the Potential Difference, Current, and Length of the Electric Arc," in which she reviewed in a lucid and interesting manner the history of the investigations which have been made in the past, in regard to the law connecting these three functions of the electric arc. The researches of Edlund, Peukert, Thompson, Frölich and others were criticised in the light of most recent investigations, and the present state of knowledge of the subject, as embodied in the refined and well-nigh exhaustive researches of Mrs. Ayrton herself, was briefly summarised. For further particulars of this important line of electro-technical research, we cannot do better than refer our readers to the series of articles now being communicated by Mrs. Ayrton to our columns. In the discussion which followed the reading of this Paper, some uncertainty seemed to exist as to the proper mode of measuring the length of an electric arc. Mrs. Ayrton had taken the distance between the tip of the negative carbon and the plane of the crater edge of the positive carbon, as the length of the arc; but Prof. FitzGerald suggested that possibly if the actual distance between the carbon surfaces were taken, there might be better agreement between the results of various experimenters. Mr. F. G. Baily remarked that with the method of measurement chosen, it was possible to have a negative length; viz., when the tip was pushed well up within the crater. Dr. Thompson stated that he had measured the arc length in the same way as Mrs. Ayrton, and suggested that it might be well to see what order of results would be obtained if the slant distance from tip to crater edge were measured, instead of the normal distance to the plane of that edge.

Prof. Ayrton next read a Paper "On the back E.M.F. and True Resistance of the Arc," in which he showed that the evidence which had from time to time been put forward in favour of a steady back E.M.F. in an electric arc was inconclusive. He and Mr. Mather, a joint author of this Paper, had obtained evidence of a species of negative resistance of the arc; indeed, a physical quantity of which it is not easy to have a clear comprehension.

After Prof. Ayrton had described an instrument for testing the strength of a magnetic field in air, a Paper "On the Velocity of Light in Rarefied Gases through which an Electrical Discharge is Passing" was contributed by Mr. E. Edser and Mr. S. G. Starling. Researches had been undertaken to discover whether any effect on the velocity of light through gases, of various degrees of rarefaction, takes place when an intermittent current is passed in the direction of the rays of light, or in the opposite direction, through the gas. Negative results were obtained.

The proceedings for the day were concluded by the reading of a Paper "On the Hysteresis of Iron in an Alternating Field," by Mr. F. G. Baily, in which the author described some researches on the relation of hysteresis to the limits of the magnetic induction cycle, but at this late stage of the sitting only scant justice could be done to this useful Paper.

Wednesday, September 18th.

The chief item of electrical interest on the Wednesday programme, in Section A, was the suggestion, by the Electrical Standards Committee, of a set of new units and names for magnetic quantities. Unfortunately, however, the far-reaching interests of this subject were not effective in bringing the practical man to Ipswich; and, except that he had already spoken through the medium of the technical press, his opinions in this matter would have been unknown to those who took part in the creation for him of these new units. It is to be regretted that dynamo builders and other practical electrical engineers were not present, to hear and take part in the discussion. It is for the convenience of the practical engineer that these units have been proposed; scientific men, if they are left to consider only their own scientific interests, would probably vote in favour of the much more rational system of units with which the name of Mr. Oliver Heaviside is inseparably connected. One of the most striking features of the discussion, in fact, was the leaning shown by many of the speakers, towards these Heavisidian units; and the general impression seemed to be that, though it might be too late to introduce them commercially, yet they carried great scientific weight. The units proposed by the Committee have already been summarised in our columns, last week; and this week we give an abstract of the discussion.

After the conclusion of the proceedings in connection with the proposed magnetic units, Mr. J. M. Barr read a Paper "On Some New Methods and Apparatus for the Delineation of Alternate-Current Wave Forms," which he had contributed in conjunction with Messrs. W. B. Burnie and Chas. Rodgers. An abstract of this Paper will be found in our columns. In the discussion which followed, Prof. Ayrton gave a lucid and interesting account of the various forms of wave tracers which have been devised, including that described in the Paper and one invented by himself in conjunction with Mr. Mather. Prof. W. M. Hicks called attention to the utility of these instruments, in that they enabled the form of the alternate current wave to be directly read by an unskilled person, such as a man in charge of a small station.

The proceedings in Section A were brought to a close by the reading of a Paper, by Mr. E. H. Griffiths, "On Some Recent Improvements in Measurements of High Temperatures." The Paper described a number of electrical thermometers and pyrometers which have recently been acquired by Kew Observatory, and which were on exhibit. It is a matter for congratulation that the authorities of Kew Observatory have arranged thus for the standardisation of platinum electrical thermometers, and the best thanks of the electrical profession are due to Mr. Griffiths for the energetic action he has taken in getting this department established.

ON SOME NEW METHODS FOR THE DELINEATION OF ALTERNATE-CURRENT WAVE FORMS.*

BY JAMES MARK BARR, W. BECKIT BURNIE AND C. RODGERS, B.SC.

With the progress of alternate current research it becomes more and more necessary to have a reliable, rapid and accurate means of determining the wave forms of currents and potential

* Abstract of Paper read before the British Association at Ipswich, Section A.

Digitized by Google

differences. The method now generally in use—namely, the determining of a number of points on the curve and subsequent drawing of a line through these points—though accurate, is tedious, and requires a skilled experimenter. What we need is an apparatus which will automatically record the shape of the wave.

Some years ago Dr. Frölich attempted to use an optical arrangement for showing the shape of the wave. This apparatus consisted of a telephone receiver, the coil of which carried the alternating current, and to the diaphragm of which a mirror was fixed. The diaphragm vibrated with the variations of the current and a beam of light reflected from the mirror, at any moment indicated by its deflection, the intensity of the current in the coil of the receiver. This beam of light fell upon a revolving mirror which imparted to it an independent motion at right angles to that due to the vibrations of the telephone diaphragm. By this means there was traced upon a screen a luminous wave form. Had this arrangement worked satisfactorily, the wave form could have been photographed, and a permanent record instantaneously obtained; but it was rendered totally useless for ordinary frequencies by errors due to the inertia of the moving parts.

In the present Paper we propose to describe an apparatus which we believe overcomes these difficulties, and automatically records with great rapidity the wave form. We employ a combination of two motions at right angles of a spot of light relatively to a screen. An ordinary contact disc is used *but the contact brush is moved slowly and continuously through its successive angular positions.* Contact is thus made each time at a slightly different position of the armature. Thus the potential difference at each contact differs slightly from that at the preceding contact. This potential difference is used to charge a condenser across the terminals of which is connected either a reflecting electrometer or a high-resistance galvanometer.

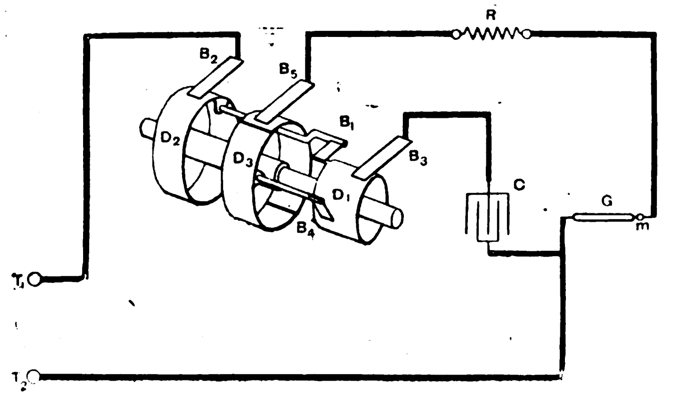

Fig. 1.

The deflection of the instrument so used follows the value of the potential difference of the wave form to be determined, and accurately follows it, for the mean rate of variation of the potential differences between the terminals of the condenser is exceedingly small in comparision with the rate of change of the electromotive for to be investigated. This deflection gives us one of the component motions. The other motion of the light spot is made to be proportional to the angular movement of the contact brush.

Fig. 1 shows the arrangement of the contact disc and accessories, a galvanometer being used—for which an electrometer might be substituted. In this diagram, for the sake of clearness, the vulcanite foundation work is omitted and the brass only shown. Our motor having four poles, we have used two knife-edge contacts placed diametrically opposite, which give us one contact per wave.

D_1 is the contact disc, which is rigidly fixed to the shaft of the dynamo or motor, and to it are attached the knife edges just mentioned.

The rings D_2 and D_3, and the rods and brushes B_1 and B_4, are mounted on one piece of vulcanite loose upon the shaft, and are revolved slowly.

The brush B_1 is joined to the ring D_2, with which the brush B_2 is in permanent connection, so that when the brush B_1 makes contact with the knife edges the condenser C is charged to the potential difference between the terminals T_1, T_2.

The condenser is throughout the whole revolution of the disc D_1 discharging through the galvanometer G by way of B_1, B_4, B_5, and the resistance R.

As the brushes B_1 and B_4 are moved slowly round, a succession of charges passes through the galvanometer, the value of each of which is proport onal to the instantaneous electromotive force, and the required movement of the galvanometer is obtained. The relative movement of the spot of light at right angles to that due to the galvanometer may be produced in a variety of ways—by a moving screen, by a revolving mirror, or, as in the apparatus which we have constructed, by an oscillating mirror. This mirror is shown in Fig. 2, which is a plan of the general arrangement, and is marked M. Mechanically connected with the disc D_2, D_3 (Fig. 1), and moving with the same angular velocity, is a cam marked K, which is shown in Fig. 2. The mirror M is pivoted about a horizontal axis, and is oscillated by the arm *a*, which bears on the cam. The arm is kept pressed against the working edge of the cam by the spring S. If the edge of the cam is properly shaped, the horizontal motion of the spot of light in synchronism with the angular motion of the brush is obtained.

We have now two motions at right angles, and by combining them during the oscillation of the mirror M in one direction we cause the spot to trace out a wave form on the screen P. The spot of light, however, during the return oscillation, would trace the wave reversed, and interfere with the true wave image. In order to prevent this the ring D_3 (Fig. 1) is discontinuous, so that the brush B_5 during the return oscillation, and the galvanometer circuit being incomplete, *the spot draws the zero line.*

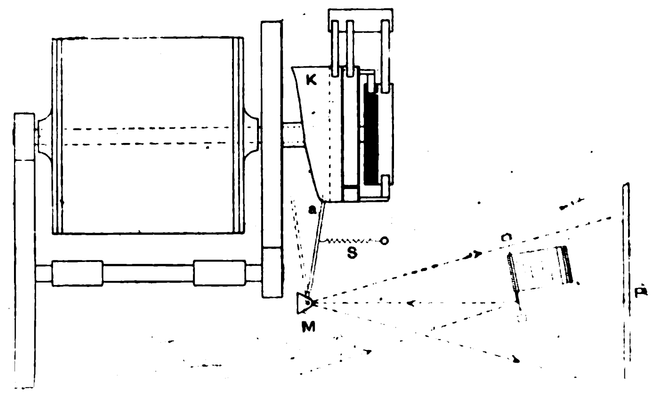

Fig. 2.

By placing a piece of sensitised paper or a sensitive plate on the screen, a permanent record of the course of the spot is obtained. The angular velocity of the moving brushes may be made so small that a well-damped instrument, even of long period, may be used. For use with an ordinary electrometer the plane mirror may be made to oscillate about a horizontal axis, and a curve drawn the zero line of which is vertical.

The cam may be dispensed with, and the screen itself moved either horizontally or vertically with gearing. Or a cylinder covered with sensitive paper may be attached to the moving brushes, and the deflection of this made to move the spot axially on the cylinder. But there are certain disadvantages attached to this method of experimenting which made us decide to construct the apparatus with the cam. There have been brought out lately several methods for building up current and electromotive force wave shapes. In using this apparatus during the process of building up wave forms the required shape may be drawn upon the screen, and the course of the spot of light observed, it being noted wherein it differs from that curve, and steps being taken to ensure a close coincidence. With the form of apparatus in which the cam is not used this process is more difficult.

Digitized by Google

A short time ago Dr. Fleming published a new and ingenious method of plotting wave forms with polar co-ordinates, and of directly obtaining therefrom the root mean-square value. Our apparatus may be easily modified so as to obtain a record of one of these polar waves. For this purpose the slow-moving disc must be mounted on the extreme end of the shaft, and a sensitised screen must be fitted thereon. The instrument must be so placed that the zero position of the spot of light on the centre of the disc and the deflection along one of the radii. The curve traced will then be of the required form. By a system of mirrors it would be possible to obtain the same result with the screen fixed, but this appears to offer no special advantages.

The galvanometer which we have up to the present used with our apparatus is of the Ayrton-Mather type, with a horizontal coil, but no silver tube for damping. The coil is wound with 260 turns of wire 1·4 mils in diameter with a resistance of 400 ohms. The period is small, being about $\frac{1}{30}$th of a second. The damping is effected by a light glass arm dipping into an oil vessel, the height of which can be adjusted.

An electrometer would have been preferable, but it is difficult to obtain an electrometer of sufficiently small period. For tracing the wave very slowly an electrometer may be used, but one of the advantages of our method over the methods in

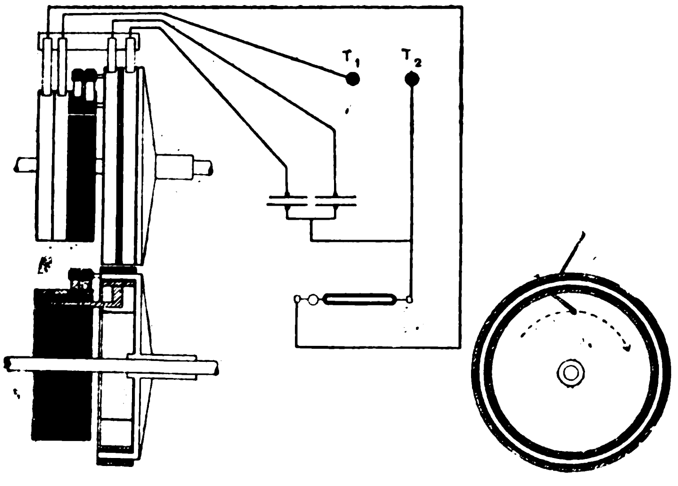

Fig. 3.

ordinary use is the rapidity with which the wave may be traced. In many experiments there is a variation of speed with time, against the effects of which it is necessary to guard, but in tracing a wave in a few seconds no appreciable variation of speed can take place.

If the spot of light were made to tr ce out the wave form sufficiently rapidly the curve would appear as a continuous luminous line. This can be effected with the apparatus, as it now stands, with *high* frequencies. With low frequencies, however, that is impossible. For instance, with a frequency of 80 alternations per second we obtain 80 contacts per wave. But since for the line to appear continuous the slow-moving disc must make at least five revolutions per second, the number of contacts cannot exceed eight per complete period or four per half wave, an obviously insufficient number.

We have in Fig. 3 a diagram illustrating a method by which this difficulty is overcome. As before, the apparatus consists of two discs—one moving at the speed of the motor and the other a slow-moving one. The slow-moving disc carries two collecting rings, two brushes, and an internal four-part commutator. Each collecting ring is connected to a pair of opposite commutator segments, and the slow disc carries two brushes, which bear on the fast disc and are connected one to each collecting ring. The fast disc also carries two collecting rings—one connected to the knife edge and the other to the fast revolving brush, which bears on the four-part commutator of the slow-moving disc. The two brushes carried by the slow-moving disc are slightly in advance the one of the other, and the slow-moving disc is rotated so as to have a definite speed relation to the fast disc. The two condensers are charged in rapid succession as the knife edges pass the brushes, and during the remainder of the half revolution are discharged in succession through the four-part commutator, the fast revolving brush and the galvanometer. The effect is to get twice as many discharges through the galvanometer per wave as is obtained with the apparatus shown in Fig. 1. Three or more condensers can be used, the total number of contacts per wave obtained being proportional to the number of condensers used. For all ordinary purposes, however, the apparatus with one condenser will be found not convenient.

In conclusion, we must acknowledge our indebtedness to Prof. Ayrton and Mr. Mather for their kind advice and to Mr. W. Duddell, one of our fellow students, for his help during the construction of the apparatus.

MAGNETIC UNITS.

BRITISH ASSOCIATION DISCUSSION.

After the recommendations of the Electrical Standards Committee on the subject had been read and amplified by Dr. Oliver Lodge, a communication "On the Choice of Magnetic Units" was made by Dr. Silvanus Thompson. An asterisk denotes that the speaker has revised the report of his remarks.

*The subject, he said, was of such importance that he thought it desirable it should be discussed as fully as possible before any definite conclusions were arrived at. With this object the views of men who daily use magnetic quantities had been invited, and were freely expressed in letters to *The Electrician*, copies of which had been distributed to members. The ohm, volt and ampere had taken root, because their magnitudes were suitable for practical requirements. If, however, magnetic units were chosen of unpractical size, such units would die at once, and never be of service to the industry. In his opinion the *magnitudes* of the units were of far greater importance than the *names*, for the names were only details. No doubt they were important details, and unless judiciously chosen might give rise to international jealousy.

For industrial purposes a unit for "total lines" was greatly needed, since a good idea of the dimensions of a plant was given to practical men if the number of lines be known. At the Chicago Exhibition the largest machine shown had a total flux of 15 million (15×10^6) C.G.S. lines, whilst the smallest had about forty thousand (40,000), the former being a large generator and the latter a small fan motor. Since that time larger machines have been built, having, say, 60 to 80 million lines. The usual density at which wrought iron was worked being 15,000 to 17,000 C.G.S. lines per square centimetre, or between 90,000 and 100,000 per square inch, the total flux gave a fair idea of the section of the magnets. At present the *line* was the unit of magnetic flux, and originally this small unit was of convenient size, because only small quantities of magnetism were then dealt with. The chief objection against its use now was that we had no prefix to carry us beyond the sixth power of 10 (megaline = 10^6, or 1 million lines). The Electrical Standards Committee now suggested 10^8 C.G.S. lines as the unit, and this he (Dr. Thompson) thought ought not to be accepted without good reason. The reason *for* proposing this unit had been stated by Dr. Oliver Lodge to be because it fitted in with the system of practical units at present in use, for a volt is generated when lines are cut at the rate of 10^8 per second. *Against* the adoption several reasons might be given. In the first place, the unit was too big, and would result in all fluxes being expressed as fractions, usually very small fractions. In his opinion it would be much better to have a small unit, and express larger fluxes by prefixes, such as *kilolines* for 1,000 C.G.S. lines, and *megalines* for 1,000,000 such lines. Another reason was that the American Institute of Electrical Engineers had already suggested a system of magnetic units not the same as that now proposed by the Committee, and had moreover used the name "weber" to mean one C.G.S. line. He did not see why the "line" need be rechristened, but this might be left open to further discussion, and we certainly had already the right to use the terms kiloline and megaline.

Speaking of the second unit to be defined, Prof. THOMPSON said the "ampere-turn" had been already adopted universally by practical men as the unit of magnetic potential, although Dr. Hopkinson and others multiplied by $4\pi/10$ to get C.G.S. units. In most cases curves were employed to pass from cause to effect (magnetic potential to magnetic lines), so why not adopt such a scale in plotting the curves so as to pass direct from ampere-turns to magnetic lines? Even if the "gauss" proposed (one C.G.S. unit) be adopted as the unit, he believed practical men would still scale their curves in ampere-turns. For some purposes, no doubt, the ampere-turn would be ridiculous, as, for example, in work relating to permanent magnets, and here the "gauss" would be appropriate. A reason *for* adopting the unit and name proposed by the Committee was that they met a want. *Against* the proposition was the fact that a name had never been given to a C.G.S. unit before, but only to multiples or submultiples of such units. At the

Digitized by Google

B. A. Committee, in 1881, one of the reasons why one-tenth of a C.G.S. unit of current was taken as the practical unit (the ampere) in preference to the C.G.S. unit, was to avoid giving a special name to a C.G.S. unit; the fact that glow lamps required currents of about one-tenth a C.G.S. unit was another reason. In America the name "gilbert" had been proposed for the unit now under discussion, and it was a pity to come into conflict with our friends across the Atlantic on this point. At the same time a word of one syllable, such as gauss, was preferable for magnetomotive force, and a word of two syllables for the resulting flux; because the quantities were somewhat analogous to electromotive force and current, for which words of one and two syllables respectively (volt and ampere) were in common use. Consequently he thought our "gauss" should be retained and the American definition of "weber" agreed to.

In his opinion it would be a great pity to attempt too much christening at once, and he recommended that only the two units for flux and magneto-motive force be settled, and the rest be allowed to settle themselves. Unless this was done some of the units would soon become antiquated.

Referring to the system of "rational" units proposed by Mr. Oliver Heaviside, Dr. THOMPSON said the more he read of Mr. Heaviside's work the more was he impressed by the importance of the suggestions made. Mr. Heaviside's units were based on *action in the medium* instead of *action at a distance*, the foundation of the C.G.S. system. If absolutely pure substances could be got and the temperature reduced to absolute zero, then the properties of electric currents *in* wires would disappear, and all the phenomena be *in the medium* surrounding the wires. Apart from chemical action at electrodes in a gap in the circuit, the only action of the current then remaining was the magnetising force it excited in the medium. In any rational system of units the unit of magnetic potential would be the same as the unit of current. Instead of defining magnetic pole by the equation

$$f=\frac{m_1 \times m_2}{d^2},$$

Mr. Heaviside uses

$$f=\frac{m_1 \times m_2}{4\pi d^2},$$

and consequently his unit of magnetism was smaller than the C.G.S. unit in the ratio of 1 to $\sqrt{4\pi}$. If the 4π be omitted in the above equations, it kept cropping up elsewhere. In order to form a consistent system of units, Mr. Heaviside had put in the 4π at the beginning in the fundamental equations, and so saved it from producing further interference. Starting from this basis, a new set of derived units resulted, which were related to the present units as shown below:—

1	"rational"	volt	=	3·544	present volts.
1	"	ampere	=	2·822	" amperes.
1	"	ohm	=	1·257	" ohms.
1	"	unit of magnetism	=	0·28205	" units of magnetism.
1	"	magnetic line	=	"	" magnetic lines.
1	"	unit of magnetic potential	=	"	" units of magnetic potential (gauss).

A coil having 10,000 "rational" ampere-turns will exert magnetic potential of 10,000 "rational" gausses, and will be equivalent to 28,205 of our present ampere-turns which $\left(\times \frac{4\pi}{10}\right)$ exert a potential of 35,440 gausses.

By adopting this system of units the relations between the magnetic units would be simplified. In his (Dr. Thompson's) opinion the change would not be very difficult. But the fact that we might at an early date have to remodel our whole system of C.G.S. units on the plan suggested by Mr. Heaviside was a very strong reason for taking at the present time a minimum of action. He therefore hoped we should proceed very slowly.

*Prof. AYRTON said Dr. Thompson in his excellent address had given reasons why the recommendations of the Electrical Standards Committee should not be adopted. He himself wished to look at the question from the opposite standpoint. Referring to the fact that the American Institute of Electrical Engineers had already chosen units and names for the more important magnetic quantities, he said, although he had the greatest admiration for American methods and American "goaheadedness," he thought they had gone ahead too fast in this matter. For at the International Congress held in their own country in 1893 it was unanimously decided by the Chamber of Delegates that the C.G.S. system of magnetic units was sufficient for practical requirements. Shortly afterwards the American Institute of Electrical Engineers made a communication to the Institution of Electrical Engineers suggesting names for magnetic units, although the recent Congress said such action was unnecessary. In reply, the Institution of Electrical Engineers, acting in accordance with the decision of the Chicago Congress that the time was not yet ripe for selecting practical magnetic units and giving them names, deprecated the proposals made by the American Institute, but in spite of this the names had been given. Under these circumstances he did not think we were bound to accept the names and definitions provisionally adopted on the other side of the Atlantic, especially as the units chosen did not form a consistent system with the volt, ampere and ohm. Dr. Thompson had complained that a "weber," equal to 10^8 C.G.S. lines, was a unit much too big for practical use. On the other hand, he admitted that since the Chicago Exhibition the total flux of the largest machines made had increased from 15,000,000 C.G.S. lines to something like 80,000,000. If this rate of increase continued we should soon have machines with total fluxes equal to one or more "webers" (100,000,000 lines), and the objection as to size of unit became of less importance. The adoption of the "fared" as the practical unit of capacity had never been found inconvenient, although it was a unit so huge that no commercial condenser had ever been made, or was ever likely to be made, having a capacity approaching the unit. The submultiple "microfarad" proved quite satisfactory in practice. Surely it was best to have all the practical units of one system. As "farad" caused no difficulty, he did not see why the proposed "weber" should. In Dr. Thompson's opinion the 1881 Congress did not change the unit of current so as to make it equal to the C.G.S. unit, because one-tenth of that unit was approximately the current taken by glow lamps then used. Being a member of that Congress, he (Prof. Ayrton) could say that the true reason for adopting the present ampere was so as not to change the size of the unit then in practical use, for such a change would have caused great inconvenience to the industry. Now, however, Dr. Thompson had suggested a far more radical change in proposing to alter, not merely the size of a unit, but the fundamental character of the equations on which the C.G.S. system was based. Interesting as the suggested alteration was from a theoretical standpoint, the question to be answered was not what might have been done 30 years ago, but what would be best under present circumstances. He was pleased to hear that Dr. Thompson was at one with the Standards Committee as regards the definition of the "gauss."

*Dr. JOHNSTONE STONEY thought the differences expressed by the previous speakers could be reconciled by the simple expedient of using suitable terminations. All the terms hitherto given to electromagnetic units derived from the names of investigators, such as "ohm," "volt," "ampere," "farad," belonged to one consistent series of systematic units, commonly called the "ohm" system or the "practical" system. This established a very convenient practice, which he thought it undesirable to infringe by giving terms derived from the names of scientific men to any units not belonging to that particular series. At the same time it was an inevitable consequence of keeping to systematic units that some would be far too large or far too small for business or laboratory practice. This difficulty he proposed to meet by decimal multiples or submultiples of units of the ohm series, wherever the units of that series were inconveniently large or small, indicating multiples by the affix *-ane* or *-ain*, and submultiples by *-et* or *-ette*. Thus the *faradet* would signify some decimal submultiple of the farad. The microfarad in common use is the sixth of these faradets, but throughout an investigation it would be sufficient to say that the capacity of the condenser or cable under consideration was so many faradets, it being stated once for all that the sixth of the decimal series of faradets was being employed. In some laboratory work he had found it convenient to use a measure a thousand times smaller than a microfarad, but still called it a faradet. It was quite enough to record once for all in his note-book that the ninth faradet was being used. In the proposed nomenclature

The C.G.S. unit of	resistance	=	the	ninth ohmet.
"	" electromotive force	=	"	eighth voltet.
"	" current..............	=	"	first amperane.
"	" capacity	=	"	ninth faradane (a truly immense unit),

and so on.

On the foregoing grounds he dissented, as a member of the Committee, from the proposal of the Committee to give such names as weber or gauss to any other than units of the ohm series. He proposed that the Committee should pick out those decimal multiples and submultiples of the ohm series of units which were most convenient in practice, and give them such names as gaussane or gaussette, reserving names such as gauss for the units of the ohm series. The suggested affixes with slight modification of spelling would answer in German, French and English; and if in any other language *-et* or *-ane* were unsuitable, other affixes consonant with the genius of the language might be substituted without risk of misunderstanding.

Dr. FREDERICK BEDELL, of Cornell University, Ithaca, N.Y., agreed that the two positions were reconcilable, and thought it very desirable that national prejudices should not come into the question. He did not wish to take credit for what the Americans had done, nor be held responsible for their sins, but hoped that a satisfactory agreement could be arrived at. The 4π question was not now before the meeting, for they were not quite ready to take it up yet. He might, however, mention that the question was analogous to whether unit cube, or a sphere of unit radius should be taken as the unit of volume. Referring to magnetic units he said that, in the equation

$$\text{induction}=\frac{\text{magnetomotive force}}{\text{reluctance}},$$

the American Institute of Electrical Engineers used the C.G.S. units with names, thus:—

$$\text{webers}=\frac{\text{gilberts}}{\text{oersteds}},$$

whilst Prof. Thompson would employ the same quantities with different names, viz.:—

$$\text{webers}=\frac{\text{gauss}}{\text{units of reluctance}},$$

The proposal of the Committee was to use a large unit of magnetic flux and call it a weber, and choose the unit of reluctance so that the latter equation held good. The suggestions made by the American Institute were the same as those of Prof. Thompson except as to names. In America "gauss" had been used as the unit of flux density, *i.e.*, webers per square centimetre. In conclusion, Dr. BEDELL said he endorsed Prof. Thompson's views, for the units he proposed were best suited in size for practical purposes.

Prof. EVERETT said the question must be considered from both the theoretical and practical side. No doubt the present system of units was not so perfect as it might be, but in the meantime we must use the best obtainable. He agreed with Mr. Oliver Heaviside in theory, but if his

Digitized by Google

system of electrical and magnetic units be adopted the harmony that existed between all absolute systems of units (gravitation, &c.) would no longer hold. The present absolute system defined unit pole (or mass) so that the mutual force between two poles was equal to their product divided by the area of the square on the line joining them, whereas Mr. Heaviside divided the product by the area of the sphere whose radius was equal to the line joining the poles. One of the most important results in the theory of attraction (whether gravitational, electric, or magnetic) was that *the surface-integral of normal attraction over any closed surface was equal to* 4π *times the quantity within the surface*, or $\int F\,ds = 4\pi M$; and so long as the square on the line between two poles be used in defining unit pole, the 4π must come in somewhere. If, however, Mr. Heaviside's definition be used, the 4π disappeared, and the surface-integral became equal to the quantity within the surface. On this account "rational" units simplified formulæ, and might often be used with advantage. On reading the discussion on magnetic units which had appeared in *The Electrician* he observed that the "weber" proposed by the Committee was used in practice; but, referring to the connection between weber-turns and voltage in a transformer, he gave the expression $N = \epsilon/2\pi$ (or unit frequency), where N = maximum number of webers threading the electric circuit and ϵ the square root of mean square voltage per turn. As to the suggested unit of magnetomotive force—the gauss—he thought there was no need for the name, as the C.G.S. unit was well known. The word "voltage" had, however, been found convenient, and "gaussage" would be useful.

*Prof. PERRY agreed with the recommendations of the Committee, and expressed regret that only the authority of the British Association had been utilised to bring them forward. In his opinion a general congress should have been called to settle the matter on a satisfactory basis. Six years ago (see *The Electrician*, July 31, 1891, Vol. XXVII., p. 355) he suggested to the Standards Committee the units now proposed for adoption, but did not mention names, for these were points on which great difference of opinion might reasonably exist. He was sorry to think that the Committee did not boldly face a difficulty which became greater by delay, and adopt at once Mr. Heaviside's suggestions as to rational units. He thought that it was quite possible to make the change now.

*Mr. TREMLETT CARTER said the present system of units was not such as would gain the approval of posterity, and to enlarge that system was not the proper course to pursue. All agreed that the "rational" system proposed by Mr. Heaviside was better, and this should be adopted. It would not be more difficult to do this than to introduce the metric system of weights and measures.

Mr. F. G. BAILY said there was no object in hurrying on the christening of the gauss, for he could see no use for it. The ampere-turn was already used in practice. Whether the name "gauss" or ampere-turn be given to the unit was a matter of no importance. Regarding the "weber," the general opinion seemed to favour 10^8 C.G.S. units, Dr. Thompson being the only one who preferred the little weber.

*Dr. THOMPSON, in reply, pointed out that the American Institute of Electrical Engineers said they did not want to create new units, but required names for the old ones. The names, however, had only been provisionally adopted in America. Although the ampere-turn would be used by practical men, he hoped the gauss, as proposed by the Committee, would be the unit of magnetic potential. As to the choice of the magnitude of the ampere, he said that at the York meeting of the British Association the fact of glow lamps requiring currents about one-tenth of a C.G.S. unit was brought prominently forward as an argument why one-tenth should be chosen as the practical unit, and this found favour on the Continent as being nearly equal to the current sent by a Daniell's cell through one Siemens unit. Dr. Johnstone Stoney had objected to naming units not belonging to the ohm system, and suggested affixes for multiples or submultiples of those units. He (Dr. Thompson) thought this might lead to difficulty, for terminations were not the same in all nations. He instanced the circumstances that the Italian electricians would not use the word *volt*, but called it the *volta*.

*Dr. OLIVER LODGE called attention to the fact that in the report the Committee said they wished to come to no hasty decisions, but recommended for tentative adoption the terminology which had just been discussed. The Committee had no wish to slay the ampere-turn, for it might give place to the "gauss" gradually. Similarly, both "line" and "weber" might for a time be used, and practice would decide survival. Any quantity familiarly dealt with demanded units of different magnitude; it would be inconvenient to have to state the price of an estate in coppers, or of an orange in pounds. He recollected Prof. Perry opening up the whole question of magnetic units several years ago, but did not remember exactly what his suggestions were. As to the 4π question, he himself feared that the time had grown too late for so radical although so desirable a change, but he was interested in seeing how many seemed to favour it. If there were really anything like a consensus of opinion in favour of effecting the improvement it might seriously be attempted. Perhaps some day even the objectionable decimal system of arithmetic might give place to the far more convenient duodecimal system. Prof. Ayrton had confessed to conservative feelings so strong as to cause him, so long ago as the Paris Congress, to adhere to one-tenth C.G.S. as a unit of current, because that had been for a short time in use, although there were manifest disadvantages in such usage, and although its name was then being changed from weber to ampere—a most favourable opportunity for revision; so he was not surprised to find him strongly opposing any such now serious change as that involved in putting the factor 4π into its proper place. If done at all it should be done thoroughly, and the change applied to electrical, to magnetic and to gravitational units. Perhaps, however, the best time for a revolution would be the epoch when the real nature of the etherial constants, κ μ and ν, became understood.

On the motion of the PRESIDENT (Prof. Hicks) the thanks of the meeting were accorded to those who had taken part in the discussion.

ELECTRIFICATION AND DISELECTRIFICATION OF AIR AND OTHER GASES.*

BY LORD KELVIN, MAGNUS MACLEAN, AND ALEXANDER GALT.

Experiments were made for the purpose of finding an approximation to the amount of electrification communicated to air by one or more electrified needle points. The apparatus consisted of a metallic can 48cm. high and 21cm. in diameter, supported by paraffin blocks, and connected to one pair of quadrants of a quadrant electrometer. It had a hole at the top to admit the electrifying wire, which was 5·31 metres long, hanging vertically within a metallic guard tube. This guard tube was always metallically connected to the other pair of quadrants of the electrometer and to its case, and to a metallic screen surrounding it. This prevented any external influences from sensibly affecting the electrometer.

The experiment was conducted as follows: One terminal of an electric machine was connected with the guard tube, and the other with the electrifying wire, which was let down so that the needle was in the centre of the can. The can was temporarily connected to the case of the electrometer. The electric machine was then worked for some minutes, so as to electrify the air in the can. As soon as the machine was stopped the electrifying wire was lifted clear out of the can. The can and the quadrants in metallic connection with it were disconnected from the case of the electrometer, and the electrified air was very rapidly drawn away from the can by a blowpipe bellows arranged to suck. This released the opposite kind of electricity from the inside of the can, and allowed it to place itself in equilibrium on the outside of the can and on the insulated quadrants of the electrometer in metallic connection with it.

Different lengths of time of electrification and different numbers of needles and tinsel were tried, but the experimenters found that one needle and four minutes of electrification gave nearly maximum effect. The greatest deflection observed was 936 scale divisions. It was found by experiment that the quantity of electricity giving 936 scale divisions was $\frac{1}{435} \times \frac{936}{122} = 1{\cdot}7637$ electrostatic units. The capacity of the can was 16,632 cubic centimetres, which gives, for the quantity of electricity per cubic centimetre, $\frac{1{\cdot}7637}{16{,}632} = 1{\cdot}06 \times 10^{-4}$. The electrification of the air in this case was positive; it was about as great as the greatest obtained, whether positive or negative, in common air when electrified it by discharge from needle points. This is about four times the electric density which the authors roughly estimated as about the greatest given to the air in the inside of a large metal vat, electrified by a needle point and then left to itself, and tested by the potential of a water dropper with its nozzle in the centre of the vat, in experiments made two years ago and described in a communication to the Royal Society in May, 1894.

In subsequent experiments, electrifying common air in a large gas holder over water by an insulated gas flame burning within it with a wire in the interior of the flame kept electrified by an electric machine to about 6,000 volts, whether positively or negatively, the authors found as much as $1{\cdot}5 \times 10^{-4}$ for the electric density of the air. Electrifying carbonic acid in the same gas holder, *whether positively or negatively*, by needle points, an electric density of $2{\cdot}2 \times 10^{-4}$ was obtained. About the same density ($2{\cdot}2 \times 10^{-4}$) of *negative* electricity was found in carbonic acid gas drawn from an iron cylinder lying horizontally, and allowed to pass by a U-tube into the gas holder without bubbling through the water. When carbonic acid gas was drawn slowly from the liquid carbonic acid in the iron cylinder placed upright, and allowed to pass, without bubbling, through the U-tube into the gas holder over water, no electrification was found in the gas unless electricity was communicated to it from needle points.

The efficiency of the electric receivers used was approximately determined. The efficiencies of two different receivers were respectively 0·77 and 0·31 with air electrified positively or negatively by needle points; and 0·82 and 0·42 with carbonic acid gas electrified negatively by being drawn from an iron cylinder placed on its side. Each of these receivers consisted of block tin pipe 4cm. long and 1cm. diameter, with five plugs of cotton wool kept in position by six discs of fine wire gauze. The great difference in their efficiency was no doubt due to the quantities of cotton wool being different, or differently compressed in the two. The authors have commenced and hope to continue an investigation of the efficiency of electric receivers of various kinds.

In addition to experiments on electric filters, the authors have made many other experiments to find other means for the diselectrification of air. It might be supposed that drawing air in bubbles through water should be very effective for this purpose, but this is far from being the case.

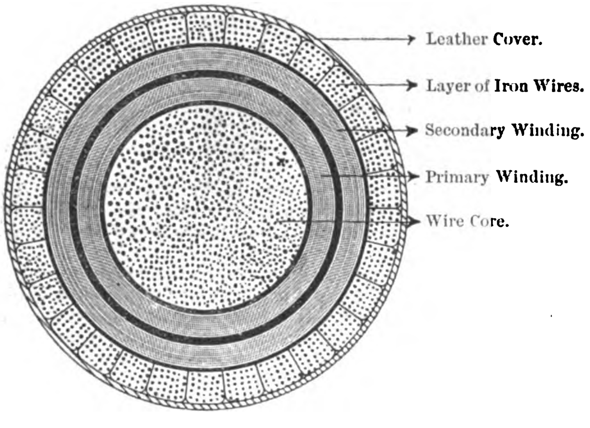
* Abstract of a Paper read before the British Association at Ipswich, Section A.

Digitized by Google

To test the effects of heat the authors drew air through combustion tubes of German glass about 180cm. long and 2½ or 1½cm. bore, the heat being applied externally to about 120cm. of the length. It was found that, when the temperature was raised to nearly a dull red heat, air, whether positively or negatively electrified, lost little or nothing of its electrification by being drawn through the tube. When the temperature was raised to a dull red heat, and to a bright red, high enough to soften the glass, losses up to as much as four-fifths of the whole electrification were sometimes observed, but never complete diselectrification. The results, however, were very irregular. Non-electrified air never became sensibly electrified by being drawn through the hot glass tubes, but it gained strong positive electrification when pieces of copper foil, and negative electrification when pieces of carbon, were placed in the tube, and when the temperature was sufficient to powerfully oxidise the copper or to burn away the charcoal. Through the kindness of Mr. E. Matthey the authors were able to experiment with a platinum tube 1 metre long and 1mm. bore. It was heated either by a gas flame or an electric current. When the tube was cold, and non-electrified air drawn through it, there were no signs of electrification. But when the tube was made red or white hot, either by gas burners applied externally or by an electric current through the metal of the tube, the previously non-electrified air drawn through it was found to be electrified strongly positive. With stronger currents, raising the tube to white-hot temperature, the electrification seemed to be considerably less.

THE MÜNCH INDUCTION TRANSMITTER.*

This instrument has been invented by Herr Postrath Münch, and is now being introduced by the German Post Office for the general use in telephony. The transmitter, of which a section is shown in the accompanying figure, contains an iron core 13cm. long and



3cm. in diameter, the wires of which are varnished with shellac. The whole core is insulated with a layer of paper, then follows the primary winding, again double paper insulation, and then the secondary winding. Each winding consists of about 10 layers, or 4,000 turns of silk-insulated copper wire 0·2mm. in diameter. To increase the effect of the transmitter, a 5mm. layer of fine iron wire is wound parallel to the iron core round the secondary winding. The resistance is about 200 ohms in the primary, and about 250 ohms in the secondary. In making experiments, a small alternator, giving 2·5 volts, was used, and by altering the periodicity from 350 to 700, the following results were obtained :—

Secondary open.	Increase of the apparent resistance of primary.
(a) Open	from 5,500 to 12,000 ohms.
(b) Closed through a resistance of 500 ohms...	„ 910 „ 940 „
(c) Short-circuited........................	„ 460 „ 490 „

The self-induction in the primary changed as follows :—

(a)	from	2·240	to	2·440 henries.
(b)	„	0·081	„	0·047 „
(c)	„	0·042	„	0·040 „

The electrostatic capacity between the two windings is extremely small, and an average of tests has given 0·00185 microfarad.

The exact "efficiency" of the apparatus in the transmission of telephone currents has so far not been ascertained, but preliminary experiments have given very satisfactory results. It has been found that even an experienced ear cannot discover the slightest difference upon the "sound-effect" of a receiver when used alternately direct or with the transmitter in the circuit. When double transmission is necessary, a slight difference is observable in the sound when the transmitters are either in or out of circuit. The ratio of the volume of the sound in the two cases is about 95%.

* From the *Elektrotechnische Zeitschrift*.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September 13, 1895.*

The American Association for the Advancement of Science.—At the annual meeting of the American Association for the Advancement of Science, at Springfield, Mass., last week, several electrical Papers were read, of which two by Dr. Pupin were, perhaps, the most important. One of the latter was on the "Flow of Alternating Currents in Cables," in which Dr. Pupin supplies a missing term in Lagrange's equation of condition expressing the law of a vibrating cord, thereby taking into account both the effect of the receiving and transmitting apparatus. The other Paper was on "The most general Relation between Electric and Magnetic Forces and their Displacements," in which an additional law is laid down, deduced from the existing two experimental laws upon which the Maxwellian theory of electricity and light rest. The theory as thus expanded, Dr. Pupin states, will explain all the various phenomena of light and electricity without any added hypotheses. Prof. C. D. Childs gave an account of some unfinished work concerning a Hertz effect corresponding to that of a diffraction grating on light, which, he believed, had thus far not been observed. The grating was made by fastening strips of tin on a wooden frame, and with two different gratings thus made, wave lengths were determined by the new diffraction method and their accuracy checked by the Righi interference method. In a Paper on "Solar Magnetic Radiation and Weather Forecasts," Mr. Frank H. Bigelow maintained that magnetic radiations demonstrate the existence of an earth crust about 800 miles in diameter, and that the sun has also a crust, thus controverting the current idea that it is wholly vaporous or fluid. The method by which these inferences are arrived at will, it is claimed, lead to means of forecasting the weather years in advance. An exuberant Paper, by R. P. Williams, was read on "An Electrolytic Process for the Manufacture of White Lead." The process as described consists of, first, an electrical preparation of nitric acid and sodium hydro-oxid; second, the action of nitric acid on lead forming lead nitrate; third, the action of lead nitrate and sodium hydro-oxid to form lead hydro-oxid; fourth, the combination of lead hydro-oxid and sodium bi-carbonate to form lead carbonate. The author claims that by this process the cost of making white lead will be but a fraction of the cost by present methods, and that the process is almost instantaneous, instead of occupying from two to six months as at present; other advantages claimed are the small area occupied as compared with the older processes, and a better quality of the product. Prof. H. S. Carhart read a Paper on the "Experimental Investigation of the Rotary Field," which consisted in the examination of the magnetic flux of the rotary field by means of iron dust phantoms.

Underground Conduit Street Railway Traction.—The statement made by President Crimmins, of the Metropolitan Street Railway Company of New York, a few weeks ago, concerning the great saving in operating expenses demonstrated on the Lenox-avenue electric line, has resulted in announcements from all the large street railway companies in New York City of their intention of adopting electric traction. President Crimmins stated that the result of operations on the Lenox-avenue road, which employs the Budapest underground conduit system, shows a saving of four cents per car mile over cable traction and eight cents per car mile over horse traction. The Third-avenue line, which is one of the most extensive in America, sprung a surprise on the public in the announcement of its intention of adopting electric traction, by stating that on a half mile addition to the present cable, now almost completed, it would employ the Budapest system. The conduit employed on this extension is so nearly a duplicate of that used in cable traction that no one, until the announcement was made, was aware that electric conductors were to be installed in it.

The Buffalo-Niagara Franchise.—The Niagara Falls Power Company has refused to accept the terms of the franchise offered it by the City Council, permitting the introduction of current from Niagara into Buffalo, which is distant about 26

Digitized by Google

miles from the Niagara plant. The proposed franchise was recently revised, and important concessions granted to the Niagara Company, but the latter apparently thinks that it is in a position to impose its own terms. In this connection it may be said that many well-informed people believe that the Niagara electrical enterprise is merely part of a huge land-jobbing scheme, the generation of power being secondary to the building up of an industrial city on the grounds of the Company.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A certain amount of correspondence has been received since and during the oral discussion at Ipswich, and it would probably be satisfactory to the authors that their letters should appear in your columns. Accordingly I enclose them.

To those who were present at the discussion it may be convenient to say that the "unofficial" sentence, which was practically quoted from Mr. Baily's letter reproduced by you on page 451 of your issue of August 2nd, should have run thus: Weber-turns = $\frac{1}{4}$ mean volts per cycle; or, more accurately, the mean voltage developed in a transformer coil supplied with sinuous currents is equal to its weber-turns divided by four times the frequency of the magnetic alternation; it being understood that "weber-turns" means the total field through the coil under consideration multiplied by the number of times it is surrounded by the wire of that coil.

But manifestly the numeric 4 requires modification whenever the magnetisation deviates from a sine law. The *maximum* sine voltage would, of course, be got by using the factor 2π instead of 4.

It would be of interest if you could get from Prof. Perry, and publish, the letter which he addressed to the Electrical Standards Committee some five or six years ago, wherein he first officially raised the whole question of magnetic units.—Yours, &c., OLIVER J. LODGE.

September 19, 1895.

P.S.—I find in the minute book of the Electrical Standards Committee (which happens to be in my hands during Mr. Glazebrook's absence), under date September 7, 1888 (at Bath), the following record:—

"Prof. Perry was requested to draw up a report for the consideration of the Committee on the definition and name of a practical unit of magnetic field."

On April 15, 1889 (at Albemarle-street), Prof. Perry's report was read and afterwards circulated among the Committee; and on December 2, 1890, it was "ordered to be printed after revision by the author."

Accordingly it makes its appearance in your columns on page 355 of Vol. XXVII., under date July 31, 1891, where it may readily be referred to.

It is interesting to note that Prof. Perry advocated the adoption of the precise unit now christened the weber, and was otherwise in fair harmony with the present action of the Committee.

The following are the letters above referred to:—

MY DEAR GLAZEBROOK: As there is some uncertainty as to my ability to attend the meeting at Ipswich, I desire to submit some remarks on the proposed new units.

The immediate and primary business before the committee is the acceptance of a definition of unit inductance. We have agreed to its name *henry*, but we have not accepted the definition based on that which was decided on at Chicago in the following terms:—

> "Resolved,—That the several Governments represented by the delegates of this International Congress of Electricians be, and they are hereby recommended to formally adopt as legal units of electrical measure the following. . . . As the unit of induction, the *henry*, which is the induction in the circuit when the electromotive force induced in this circuit is 1 international volt, while the inducing current varies at the rate of 1 ampere per second."

The why-not is not clear from Prof. Oliver Lodge's remarks. It was sanctioned by Helmholtz, Mascart, Rowland, Ferraris; and adopted unanimously by all the other delegates, European and American, present at Chicago. It is said to be lacking in simplicity, to fail in emphasising the variability of L, and to be detached from the permeability of the circuit. Prof. Lodge would rather define it with reference to magnetic units as expressed by the equation **N** = LC, **N** being total induction, whose practical unit 10^8 C.G.S. lines he proposes to call a "weber." Thus the "henry" can be defined as a "weber" per unit C.G.S. current. But surely this is more complicated than the Chicago definition, which really implies variation, and is independent of any further additions to our practical units. The "henry" filled a want. It is already in daily use and is much appreciated. Nothing has been gained by the delay in accepting the Chicago definition. But do we want any further nomenclature?

The American Institute of Electrical Engineers, a very large and influential body to whom we are indebted for the "henry," have provisionally accepted the following units:—

> *Gilbert.*—C.G.S. unit magnetomotive force.
> *Weber.*—C.G.S. unit of induction.
> *Oersted.*—C.G.S. unit of reluctance.
> *Gauss.*—C.G.S. unit of induction density.

Prof. Lodge has ignored these proposals, and discusses the *gauss* as applied to unit magnetomotive force, and the *weber* as applied to 10^8 C.G.S. lines of induction.

The American proposals are certainly a departure from our past practice. We have not hitherto christened the C.G.S. electrical or magnetical units, but only the practical ones. Moreover, it is by no means clear that we want a gilbert, an oersted, or a gauss as defined by the American Institute of Electrical Engineers. The weber, however, made equal to 10^8 C.G.S. lines, is both practical and useful. The real practical unit of magnetomotive force is the ampere-turn. Do we want to change this, or even to give it another name?

The system of B.A. units is by no means perfect. If we commence to tinker it we may spoil it. We have lost the lead chiefly by our own dilatoriness. Changes can now be effected only through International Congresses. The principal defects of the system are:—

(1.) The unfortunate selection of 10^8 C.G.S. units as the practical unit of E.M.F. The volt ought to have been 10^9 C.G.S. units. It would have made the ampere and C.G.S. unit current the same and minimised labour.

(2.) We have assumed both μ and κ (specific electric inductivity) to be unity in air, which is not only quite artificial, but absolutely wrong. We have no accepted definition of μ, nor are we agreed either as to its nomenclature, or even as to its physical character.

(3.) Some object to the presence of π, and would relegate, it by more artificialism, to a less intrusive place.

(4.) The farad as a name is lost owing to its enormous magnitude. It would have been well if we had called the present microfarad the farad. The present farad would then have been the megafarad, and brevity would have been secured.

(5.) The determination of the intrinsic value of the joule, which depends on the heat equivalent of work, and which has now reached a stage where a definite figure can be accepted as reliable, though perhaps not quite so accurate as that of the ohm.

(6.) This would lead to a definite intrinsic value of the *watt*, and therefore of the *kilowatt*, which would replace the present irregular and meaningless *horse-power* and give us an international coherent and universal unit of power.

My view is that we should at the present meeting accept the Chicago definition of the *henry*, and if a practical magnetic unit is really necessary it should be the flux = 10^8 C.G.S. lines of magnetic force. Whether this unit be called the *weber* or the *gauss*, or by any other name, is a matter of little consequence. It should have a definite name, for names are most successful in securing true conceptions of concrete ideas, in furthering exact science, and in popularising practical units. The "weber," if selected, would be as successful in familiarising the workman to the conception of *magnetic flux* as the "ampere" has that of *electric current*.—Yours, &c.,

S.s. "Monarch," August 20, 1895. W. H. PREECE.

DEAR LODGE: I should have liked much to be present at the discussion on Units in Section A this morning, but I must go home.

I should like to say a word in favour of regarding (as I believe you would) from the beginning *electric inductivity* and *magnetic inductivity* as fundamental quantities for the medium, and denoting them by k and μ respectively.

Thus if E, H be the electric and magnetic field intensities, we should have k E, μ H as the electric and magnetic inductions. (*Induction* is not a very good name for the quantities here, but I suppose it cannot be altered.)

If k_0, μ_0 be the inductivities for the standard medium, whatever it is, we should have k/k_0, μ/μ_0 for the electric and magnetic *permeabilities*. Thus the magnetic *permeability* (so say) of a piece of iron would be, as Lord Kelvin originally defined it, the ratio of the magnetic *force* in a crevasse cut at right angles to the lines of magnetisation to the magnetic *force* in a narrow cylindrical cavity along the lines of magnetisation, and would, therefore, be a mere number. Also we should have $\mu = \mu_0 (1 + 4\pi\kappa)$, where κ is a number.

A great sea of trouble would be avoided if this plan were followed consistently and from the beginning in teaching. Nothing is more bewildering to students than to have k defined, as it very often is (in Maxwell even), as a mere ratio (the ordinary K), and then when they go on to the ordinary electromagnetic system of units in which μ is taken as a mere ratio, to find that $1/k$ *has the dimensions of the square of a velocity!*

With your views generally as to L, &c., I quite agree. As to rationalisation, we have gone much too far to turn back now. And I think the inconvenience of the 4π factor in electric and magnetic work, though it is sensible, has been exaggerated.

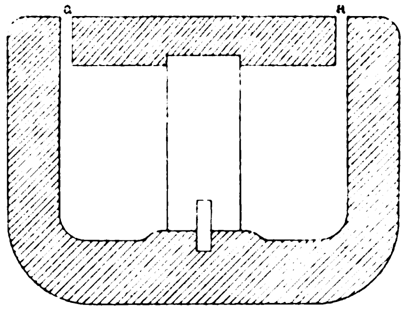
I am sorry to trouble you with this, but I have been so strongly convinced of the desirability of the fundamental reform referred to above, that I felt compelled to write to you.—Yours, &c., A. GRAY.

121, Norwich-road, Ipswich, Sept. 18, 1895.

Digitized by Google

Dear Professor Lodge: Will you kindly permit me to refer to the Memorandum on "Magnetic Units" which you have drawn up for discussion in Section A? The particular point I wish to mention is the "desirability of introducing a 'gauss unit' as an aid to teaching," &c., p. 9, line 25.

Some four years ago I showed and described an instrument which may fulfil the purpose. I called it "a permanent magnetic field" (*Phil. Mag.*, 1892, I think), and gave figures showing that the value had not changed for many months. The rough sketch enclosed will give you an idea of the arrangement, and perhaps recall it to your mind, as I had the pleasure of showing it to you.



Briefly, it is a straight magnet having two pole-pieces, the upper one being a disc, the lower one a hemisphere (roughly). The space *a a* is an annular ring between the pole-pieces. I look upon the instrument as a practical unit of **N** = webers, and have found it very helpful to students. The instrument has a brass cylinder arranged to fall through the air gap. On the outer face of the cylinder is wound a coil, and the ends of this coil joined to a circuit give definite values of $Q = \frac{N}{R}$ or $\int e\, dt$. Your note makes me think it, or some modification, might be used for providing a standard gauss-fall $\omega_a - \omega_b$ as given in your equation page 3.

The permissible value of induction density in the steel magnet depends, of course, on the breadth of the air gap. My earliest instrument of this form has **B** = 5 to 6,000 C.G.S. units per square centimetre. The air gap = $\frac{1}{10}$in. in breadth. Total lines = 26,000 (about) C.G.S. (I hardly remember exact figures).

Somewhat recently, I redetermined the value of this instrument for Dr. Du Bois of Berlin, and could detect no change from the initial value.—Yours, &c., W. Hibbert.

British Association, Ipswich, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Yesterday, in the discussion on Units in Section A of the British Association, I referred to a document prepared by me for the Standards Committee some seven years ago, and published by you at the Secretary's request July 31, 1891. I am sorry that my absence from England during the recent discussion in your columns has prevented my calling attention to that document. I have just now re-read the document, and beg to apologise to Dr. Lodge for my quite incorrect assertion that my suggestions were the same as those of the Committee. What I said in the document was :—

"I would suggest that the practical unit of magnetic flux (or induction or force) be 10^8 C.G.S. units, and that it receive a name. [This is the same as Dr. Lodge's *weber*.] That the magnetic permeability of air shall no longer be assumed to be unity, but in the practical system of measurement be tabulated like the permeability of any other substance—the permeability of air will be $4\pi \times 10^{-9}$; and that in future no substance shall have unit permeability. [In Dr. Lodge's system the permeability of air is 10^{-8}.] That the unit of total magnetomotive force in a magnetic circuit be one ampere-turn. The unit of magnetomotive force gradient [magnetic potential] would be one ampere-turn per centimetre. It will follow that—

"(1.) A wire 1cm. long, moving at 1cm. per second across unit field, generates an E.M.F. of one volt.

"(2.) If a wire 1cm. long conveys one ampere, the power used (or developed) in moving it across the unit field at 1cm. per second is one watt.

"(3.) A magnetomotive gradient of one ampere-turn per centimetre produces unit induction (magnetic flux or force) per square centimetre if the permeability is one.

"(4.) Change of induction (magnetic flux or force) at the rate of one unit per second produces one volt per turn of wire."

Seven years ago I stated that I saw so many disadvantages as well as advantages in my system that I did not venture to ask for more than its discussion. The resulting system is simple, but I was frightened by the radical change involved in the permeability. Dr. Lodge yesterday said nothing about permeability, but as we must take webers per square centimetre = gaussage per centimetre × permeability, the permeability of air is 10^{-8}, instead of 1, whereas in my system the permeability of air was $4\pi \times 10^{-9}$.

For many years I have used 10^8 C.G.S. units as the practical unit of induction in such equations as $V = RC + n\,\theta\,I$, where V is in volts, R in ohms, C in amperes, n the number of turns of wire, I the total induction, and θ the symbol of differentiation with regard to time. But I have always converted ampere-turns into C.G.S. units and worked in C.G.S. when dealing with magnetic circuits—that is, when actually calculating the induction per square centimetre; and as the total induction is never needed except in the use of the above kind of equation, I always divided by 10^8 to obtain I for use with volts.

I still have the opinion that I held seven years ago, that until practical men demand units there is no great need for them. I am not in opposition to the Committee or to Dr. Lodge in their publication of the *weber* and *gauss*; if they ask me to adopt them I say, "Ay, and twenty such." Yes, faith, and I will use them, "Fridays and Saturdays and all," as Rosalind says in the play.

About the adoption of Mr. Heaviside's suggestions, and employing the whole authority of the B.A. Committee, such as it is, in an endeavour to immediately get rid of 4π from our fundamental equations; about this I have no doubt whatsoever. The change must come, and "better soon than syne."—Yours, &c.,

31, Brunswick-square, W.C., John Perry.
September 19, 1895.

SMALL WATER-POWER PLANTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to your note on the subject of small water-power plants; this is a subject to which I have devoted considerable attention. There are, in my opinion, a number of small places which could be effectively and economically electric lighted, but there are a number of causes operating to prevent its being done, and of which I will mention a few.

(1st) The native conservatism and slowness to grasp a good thing which is characteristic of this country, especially of the village element. A Londoner who is accustomed to smart business would nearly be driven crazy when dealing with the inhabitants of some small towns.

(2nd) The question of expense. This need not be a very serious obstacle. Money can be found for second-rate badly-managed gas works supplying a bad article at a high price, and why not for electric lighting? As to the question of the hydraulic works, which in most cases is a very large proportion of the whole cost of a water-power scheme, there are usually in such places either saw mills or flour mills driven by water power, and an arrangement could be made with their owners to allow the use of the power during certain hours. By this means the town would avoid the outlay of a large lump sum on works. The overlapping of the "mill" and "light" load could be provided for by a small storage, either batteries or hydraulic, the latter being the method proposed by myself in the case of a number of places during the last two years.

(3rd) The cast-iron Board of Trade. It does not seem to be realised by some people that there are many places where electric lighting could be profitably employed, but which could not be made to pay were the Board's requirements fully carried out. In such cases it is usually a case of overhead wires or none, and with various relaxations of the rules referring to hours of and constancy of service at a given pressure. If when freed from some Board of Trade restrictions the small station gives a bad service, then it will very quickly be shut down by the action of the consumers, without any necessity for anyone but the Official Receiver to interfere in the business. It should not also be necessary to spend £250 and upwards to obtain a reasonable tenure of the powers obtained by Provisional Order.

What I would propose is that the licensing system should be extended in, say, the following manner. That a "licence" be issued for seven years, and renewable on the application of the owners for a further period of seven years, subject to examination and passing as to good condition and fitness as to work (regard being of course paid to commercial considerations), so that the plant could be run for the same period as on a Provisional Order, but subject to inspection every seven years.

Digitized by Google

Provision might be made for intermediate inspection on the application of the Local Authority, if it was reasonably believed that the plant was being allowed to get into a dangerous state. There are numerous other points which I might touch on, but I do not wish to occupy your space more than necessary.—Yours, &c., GEORGE T. PARDOE.

September 23, 1895.

STORAGE BATTERY REACTIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your Editorial remarks in last week's issue, in the paragraph relating to Mr. Earle's Paper on Storage Batteries, you compare the strength of acid which gives maximum capacity with that yielding maximum proportion of persulphuric acid. Other remarks are made, the general tendency being to support the idea that the explanations are to be found in persulphuric acid.

I hope to deal with this and some other matters later on, having already entered into communication with Mr. Earle on the subject. Meanwhile, may I point out that on two points your remarks are not quite correct. Mr. Earle finds best results with 1·250 acid so far as *capacity* is concerned, but not with regard to *voltage*.

Again, I think you are mistaken in suggesting that as the acid rises to 1·500, the formation of persulphuric acid nearly ceases. At this density, the maximum is passed, but it is still a long way from ceasing.—Yours, &c., W. HIBBERT.

14, Goldhurst-terrace, South Hampstead, N.W.

LEGAL INTELLIGENCE.

Jaques and Sons and Thornton v. Hemming and Co. (Limited).

Applications were made to Mr. Justice Hawkins (sitting as Vacation Judge) on Tuesday last, on behalf of the holders of first and second debentures, that Mr. Thompson, who had been appointed interim receiver, might be continued as receiver and manager of the defendant Company, who carry on an electrical engineering business at Birmingham. Mr. Marten, Q.C., for the Company, submitted that the proper person to manage the business was Mr. Hemming, the present manager. His Lordship appointed Mr. Thompson as receiver and manager in both actions, with liberty to act at once, and to raise and pay the wages next week.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Corporation of Eccles invite tenders for the supply and erection of Lancashire boilers, alternating-current dynamos and engines, cables, street boxes, &c., and transformers. Tenders must be sent in to Mr. Geo. Wm. Bailey, Town Hall, Eccles, by 12 o'clock noon on Monday next, the 30th inst.

——— The Electric Lighting Committee of the Harrogate Corporation require tenders for the supply and erection of the following plant:—(*a*) Lancashire boilers, economiser, feed pumps and accessories; (*b*) steam alternators, condensers, fittings, &c., steam exhaust feed and sundry pipes, valves, &c.; (c) switchboard and instruments; (*f*) transformers and accessories; (*g*) meters; (*h*) overhead travelling crane. Tenders, addressed to the Town Clerk, Municipal Offices, Harrogate, must be delivered by Monday next, the 30th inst.

——— The Building Committee of the Harrogate Corporation invite tenders for wiring the new Montpellier Baths for the electric light. Tenders, addressed to the Town Clerk, Municipal Offices, Harrogate, must be in by Monday next.

——— The Board of Control, Dublin, require tenders for the supply and erection of two direct-coupled steam engines and dynamos, a battery of accumulators, main switchboard, &c., for the lighting of the Purdysburn Asylum, Belfast. Tenders to Secretary of the Board, Custom House, Dublin, by to-morrow, Saturday.

——— The Dundalk Town Commissioners invite tenders for the erection and maintenance of the necessary plant for lighting the town by electricity from July 1, 1896. Tenders by October 7th.

——— The municipal authorities of Tongres, Belgium, invite tenders for the concession for the public and private electric lighting of the town. Tenders to the Administration Communale by October 10th.

TENDERS INVITED.—The Lancashire and Yorkshire Railway Company invite tenders for stores for the twelve months ending October 31, 1896. Included in the list of articles required are fog signals, india-rubber, iron castings (hydraulic and water pipes), iron chain, iron hinges, steel, and files, sundry tools, varnish, brake blocks, ironmongery, &c. Further particulars and forms of tender may be obtained at the Stores Department, Osborne street, Manchester, up to the 5th prox., between 10 a.m. and 4 p.m., and on Saturday between 10 a.m. and 12 noon. Tenders, addressed to the Secretary (Mr. C. W. Bayley), must be sent in not later than 10 o'clock on Monday, October 7th next. Some further information is given in our advertisement columns.

——— The Directors of the Great Western Railway Company invite tenders for telegraph instruments, india-rubber goods, copper, iron and steel wire, telegraph ironwork, tools and drysalteries, electric light carbons, telegraph poles, &c. Tenders, addressed to the Secretary, Paddington Station, W., by October 7th prox.

——— The Electric Lighting Committee of the Bedford Urban Sanitary Authority invite tenders for the supply and delivery of 200 cast-iron lamp columns, carriers and globes. Tenders must be sent in to the Clerk (Mr. T. S. Porter) by the 8th prox. Some further particulars appear in our advertisement columns.

——— The Corporation of Blackburn invite tenders for high-tension concentric cables, low-tension triple-concentric cables, cast-iron pipes, junction boxes, drawing-in and service boxes, &c. Tenders must be sent in to the Town Clerk (Mr. R. E. Fox), Town Hall, Blackburn, by October 5th.

——— The South Molton Shirt and Collar Manufacturing Company (Limited) invite tenders for supplying generating plant, and for wiring their factory buildings for the electric light. Tenders to the Secretary.

——— The Croydon Town Council invite tenders for wiring, and for supplying and fixing electrical fittings at the New Town Hall, Courts and Free Library. Tenders must be sent in to Mr. C. M. Elborough (Town Clerk), Town Hall, Croydon, by 4 p.m. on October 8th.

——— Messrs. Willans and Robinson (Limited) require tenders for about 600 tons of mild steel and 20 tons of cast iron for their new engineering works at Rugby. Tenders to the Secretary, Picton House, Thames Ditton, Surrey, by October 5th.

——— The Goole Urban District Council invite tenders for establishing telephonic communication between Goole and Rawcliffe Bridge, a distance of about three miles. Tenders to the Clerk (Mr. Geo. England) by the 30th inst.

——— The Direction Générale of French Posts and Telegraphs require tenders for the supply of a quantity of paper-insulated cable, in two lots. Tenders to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris, by October 10th.

——— The municipal authorities of Alexandria (Egypt) invite tenders for the concession to construct and operate a system of electric tramways in the town for a period of 50 years. Tenders by Tuesday next, October 1st.

——— Messrs. Goodbody and Co., Greenville, Dublin, invite tenders for the electric lighting of their works. Plans and specifications from Mr. W. Leake, 30, Victoria-buildings, Manchester.

TENDERS ACCEPTED.—The Sunderland Town Council have received the following tenders for the supply of plant and apparatus for their electricity works:—

High-Tension and Low-Tension Concentric Cables.

British Insulated Wire Company, Prescot (*accepted*).	Fowler-Waring Cables Company, London.
Siemens Bros. and Co., London.	Callender Company.
India-Rubber Company, „	Glover (W. T.) and Co., Salford.
W. T. Henley's Company „	

Cast-Iron Pipes and Box Frames and Wires.

Maclaren (R.) and Co., Glasgow (*accepted*).	Birtley Iron Company, Birtley.
	Mackenzie Bros., Edinburgh.
Shaw (J.) and Co., Glasgow.	Mallett and Co., London.

Stoneware Casing Boxes.

Doulton and Co., London (*accepted*).	Electric Construction Co.

Transformers.

Electric Construction Company (*accepted*).	Brush Company.
	Crompton and Co.
Johnson and Phillips.	John Fowler and Co., Leeds.
Siemens Bros. and Co.	

Meters.

British Thomson-Houston Company, London (*accepted*).	Chamberlain and Hookham, B'ham.
	Edmondson, J. A., Bradford.

——— The Oldham Corporation received 11 tenders for wiring the Central Baths, Oldham, for the electric light. The amounts varied from £32. 7s. to £53, and the lowest tender, that of Messrs. Baxendale and Co., Manchester, has been accepted.

Digitized by Google

TENDER ACCEPTED.—The Ilford District Council have given the contract for providing an electric call system in connection with the fire brigade, and establishing telephonic communication with the police, to the Consolidated Telephone Construction and Manufacturing Company (Limited), 109, Farringdon-road, E.C. The contract is for a term of five years.

TENDERS RECEIVED.—The following tenders have been received by the Cowes District Council for supplying plant for their proposed electricity generating station :—

John Fowler and Co. (Leeds)	£8,350	0	0
Siemens Bros. and Co. (London)	8,100	0	0
Greenwood and Batley (Leeds)	7,600	0	0
Thomas Parker (Limited) (Wolverhampton)	6,970	0	0
Johnson and Phillips (London)	6,650	0	0
India-Rubber Company (London)	Informal.		
Crompton and Co. (London)	6,215	0	0
Bennett and Druce (Preston)	6,150	0	0
Bennett and Druce (Preston)	4,850	0	0
Brush Company (London)	5,930	0	0
Sharp and Kent (London)	5,333	0	0
Electric Construction Company (London)	5,154	18	0

The Water and Lighting Committee referred these tenders to Mr. N. F. Dennis, the borough engineer, who recommends that the tenders of Messrs. Crompton and Co., Sharp and Kent and the Electric Construction Company be retained for a further detailed analysis. The Committee rather favour the latter tender, and the Town Council at their last meeting decided to apply for a Provisional Order.

——— The Shoreditch Vestry received nine tenders for insulated electric mains, conduits and drawing-in boxes. The tenders have been referred to the Electric Lighting Committee for consideration and report.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty will sell by public auction on Wednesday and Thursday next, October 2nd and 3rd, the surplus plant and machinery in and upon the works premises of Messrs. Smith, Beacock and Tannett, Victoria Foundry, Water-lane, Leeds. Included in the sale is a great variety of lathes and tools, overhead travellers, jib cranes, Lancashire boiler, vertical engines, smiths' hearths, anvils, staple vices, screw cutting, drilling, punching and shearing machines, &c. Catalogues may be obtained (price 6d.) on application to the auctioneers, Messrs. Wheatley Kirk, Price and Goulty, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester, or of Messrs. Smith, Beacock and Tannett, Victoria Foundry, Leeds.

APPOINTMENT.—Mr. J. Schneider has been appointed inspector of the aerial line system (from Buenos Ayres northward) and assistant electrician of the Central and South American Cable Company. Mr. Schneider was formerly in the India-Rubber Company's service.

APPOINTMENT VACANT.—An assistant in the physical department of the City and Guilds of London Technical College, Exhibition-road, S.W., is required. Salary £100 per annum. Applications to Prof. W. E. Ayrton.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Edwards and Barnes, hitherto carrying on business as metal founders and stampers at Broad-street, Birmingham, have dissolved partnership. Mr. H. C. Heard retires.

——— The partnership business of engineers and founders, hitherto carried on under the style of Peter Pilkington, at Accrington, has been dissolved. Debts by Mr. W. R. Pilkington, who continues.

NEW OFFICES.—Messrs. Julius Harvey and Co., engineers and contractors for electric light and other machinery, have opened offices at Mansion House-chambers, Queen Victoria-street, E.C.

REMOVAL.—Messrs. Oscar Moenich and Co. have removed their offices to Billiter House, Billiter-street, London, E.C.

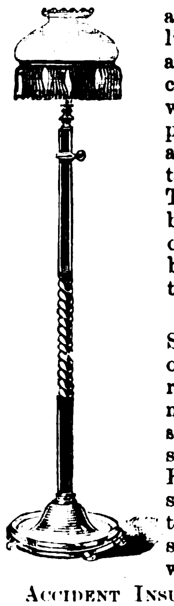
BANKRUPTCIES.—The first meeting of creditors in the bankruptcy of Dr. Joseph Whatmough, trading as an electrical engineer under the styles of D. J. Whatmough and J. and P. Dyer, and lately as W. Mason, at 39 and 41, Market-place, Oldham, will be held at the Official Receiver's office, Oldham, on October 2nd at 3 p.m. The examination of the bankrupt takes place at the County Court, Oldham, on October 18th, at 11 a.m.

——— The first meeting of creditors and contributories in the bankruptcy of Ronald A. Scott (Limited), lately carrying on business as electrical engineers at Acton, London, W., was held on Tuesday at the office of the Official Receiver for the Brentford district, Temple-chambers, E.C. As there was not a quorum at either meeting no resolutions could be passed, and the meetings were therefore adjourned for a fortnight. Afterwards the adjourned meeting of the creditors of Ronald A. Scott was held. In reply to a question as to what distinction there was between R. A. Scott and Ronald A. Scott (Limited), the Official Receiver stated that as Mr. Scott turned himself into a company in July, 1894, the creditors who had supplied goods after that date would have to prove against the Company instead of against R. A. Scott. Not that it made any difference, as in either case there was no prospect of a dividend being paid. The whole of the furniture and effects of R. A. Scott were taken over by the Company, so that he had now practically nothing ; and in the case of the Company, the whole of the assets were covered by certain debentures. In reply to questions, the debtor said he thought the Company had agreed to take over his liabilities as well as the assets. The reason he formed himself into a company was because his solicitors (Messrs. Reeves) told him it would facilitate further capital being put into the concern, and he did not form himself into a company for the purpose of giving further security to Messrs. Reeves and their clients in respect of money they had advanced. The debtor further stated that he only became aware of his insolvency in December last. In reply to a creditor, the Official Receiver stated the declaration of a dividend was not "within the range of practical politics." The debtor further stated that the Company had a lien on certain patents in connection with advertising by electricity, and if these could be sold for a reasonable sum everyone would be paid in full. This, however, is a somewhat remote possibility. The estate was left with the Official Receiver for summary administration.

LIQUIDATION.—The Official Receiver of the Worcester County Court (Mr. Luke Sharp) has issued his observations as to the liquidation of the New British Electrical Installation Contractors (Limited). The statement of accounts shows a deficiency of £4,722. 16s., plus £1,977. 12s. 2d. (added in respect of the Company's gross profits since its formation), a total of £6,700. 8s. 2d. After giving full details of the history of the concern, the secretary of the Company mainly attributed the failure to insufficiency of capital. The Official Receiver, while withholding his opinion as to the precise cause of the failure, points out that as the old Company had an authorised capital of £20,000, of which not one-twentieth part had been subscribed in cash, further information appears to be necessary as to why the new Company was ever formed. The unsecured liabilities appear to be principally for goods supplied. The Official Receiver adds that two or three of the principal creditors informed him that they were not, at the time of supplying the goods, aware that such goods were subject to the debentures immediately they reached the Company's premises. All the property is claimed by a receiver, who was appointed on behalf of the debenture-holders on July 19th last.—The first meeting of creditors takes place at 2:30 p.m. on October 1st, at the Official Receiver's office, Worcester. The contributories meeting takes place on the same day and at the same place, at 2:45 p.m.

BENNETT AND DRUCE.—This firm have recently installed the electric light at eight large sheds at the Salford Docks, at St. Joseph's Catholic Church, Preston, and at Col. Ormrod's mansion at Scorton, where a complete set of electric cooking and heating apparatus was also supplied. The firm have several smaller installations throughout the Lancashire district in hand, and have recently opened branch offices in Belfast.

BATTERY AND MOTOR COMPANY (LIMITED).—Mr. H. T. Barnett has resigned his position as joint Managing Director of this Company. Mr. Barnett will, however, continue to act as consulting electrician to the Company.



MOVABLE ELECTRIC LIGHT STANDARD.—The accompanying illustration represents a new electric light standard manufactured by Messrs Worsnop and Co., Halifax. The stand is strongly made, cheap and durable, and especially suitable for shop windows. The base is heavily weighted, so as to prevent any possibility of the lamp being overturned, and the supporting tube is of great strength and tapers from 3in. in diameter to 1in. at the top. The wire is run up the inside of the tube from the base, where it is connected by a flexible wire with one side of the window, so that the standard may be moved about at pleasure. The lamp is made in three sizes—4ft. 6in., 6ft., and 7ft. 6in.

NON-MAGNETIC WATCHES.—Messrs. S. Smith and Son, of 9, Strand, W.C., inform us that as a result of special care and attention which the firm have recently been paying to the production of non-magnetisable complicated watches, they have just succeeded in getting one of their 100-guinea split-second chronographs through the Class A tests at Kew. The tests are carried out in a special house some distance away from the observatory, so that the delicate instruments in the main building should not be affected by the very severe tests to which the watches are subjected.

ACCIDENT INSURANCE.—The Accident Insurance Company, of St. Swithin's-lane, E.C., send us a copy of their prospectus. This Company have made an important departure in insurance, as they now issue policies providing for compensation in the event of accident or disease. The Company also issue policies covering risk under the Employers' Liability Act, and act as a fidelity guarantee society.

Digitized by Google

Agency.—Messrs. Girdlestone and Co., Davies-street, Berkeley-square, W., have been appointed sole London agents for Messrs. J. P. Hall and Co., of Oldham.

Aberdeen.—Trinity Hall, the home of the Incorporated Trades of Aberdeen, is now lighted electrically. The installation has been fitted up by Messrs. P. C. Middleton and Co., School Hill, Aberdeen, and consists of about 150 lights, varying from 8 c.p. to 50 c.p.

Asylum Lighting.—The work of installing the electric light at the Sunderland Borough Lunatic Asylum at Ryhope is now complete. About 700 incandescents are used. The generating plant consists of two direct-coupled Belliss engines and Parker dynamos, and a battery of D.P. accumulators has also been installed. The laundry machinery is driven by an electro-motor, and there are several other motors employed for ventilation and for distributing the hot air by which the various wards are heated. The electrical installation has been carried out by Messrs. Edmundsons (Limited) under the joint superintendence of Mr. G. T. Hine, the architect, and of Mr. A. A. C. Swinton, the consulting engineer. The boilers and heating apparatus were supplied by Messrs. Ashwell and Nesbit.

Bedford.—The Local Government Board have sanctioned the borrowing of a further sum of £27,000 by the Council for electric lighting purposes. At the last meeting of the Council it was stated that the demand for electric current was increasing in a highly gratifying manner, and the report of the Electric Lighting Committee, recommending extensions of the mains in various streets, was adopted.

Brighton.—The electric light continues to make very satisfactory progress in Brighton. The number of customers now on the books of the Corporation is 970, as compared with 720 in 1894, 336 in 1893, and 157 in 1892. The profit on last year's working was £9,800, or, with balance in hand, £10,100, of which £5,014 has been appropriated for the loan account. For some time past the Electric Light Committee have been busy extending their mains, erecting arc-lamp standards, &c., and when this extension work is complete Western-road, North-street, St. James's-street, Queen's-road, West-street, Preston-street, East-street, Old Steine, Marlborough-place and the London-road to New England-road, will all be lighted electrically, while the lighting of the Marine Parade will complete the line of lamps along the sea front.

Bristol.—Some material for sensational paragraphs was afforded the local papers by a slight accident at a transformer sub-station in St. James's Barton on Monday. According to Mr. Faraday Proctor's account of the matter, as told to a *Mercury* reporter, the mishap was of the most trifling description. The engineers were testing the new cables for the Stoke's Croft supply at three times their working pressure—that is to say, at 6,000 volts, before permanently joining them up. For the purpose of the test temporary wires were run across the St. James's Barton sub-station, and as it was thought possible there might be some breakdown, the covers of the chamber were left off, and a man was left to watch. Directly the pressure was applied the fuses went at the central station. At the same time a telephone message was received "that something had gone wrong," and that smoke was issuing from the manhole of the transformer chamber. Those in charge then went there and found that the temporary leads had broken down and fired some pieces of creosoted wood to which they were fastened. No damage was done to the transformers, and current was being delivered from the sub-station again by 7 p.m.

Central London Railway.—It is reported that plans of the Mansion House Subway, in connection with the Bank Station of the Central London Railway Company, will shortly be laid before the Commissioners of Sewers for their approval. Access for foot passengers will be provided from Princes-street, Mansion House-street, the Poultry, Queen Victoria-street, Walbrook, Mansion House-place, Lombard-street, Cornhill and Threadneedle-street. The Company intend to commence operations on this portion of the work, and by a special provision the Waterloo and City Railway will also have access to the subway. So far as is known at present, each train will be composed of seven cars, each capable of accommodating 56 passengers, and will be lighted throughout by electricity. The distance between the Bank Station and Shepherd's Bush will be traversed in 25 minutes. It is, however, expected that many months must elapse before the plans are finally approved.

Church Lighting.—St. George's Roman Catholic Cathedral, Southwark, will shortly be lighted electrically.——Messrs. Bennett and Druce recently installed the electric light at St. Joseph's Catholic Church, Preston.

City of London College.—The Michaelmas Term of this College (White-street, Moorfields, E.C.) commences on Monday next, the 30th inst. Classes in magnetism and electricity, mathematics, sound, light and heat, chemistry, &c., are held. Accommodation for practical work is also provided.

City of London Electric Lighting Company (Limited).—This Company announce that as it has been found that the scale set forth in their circular of January 31st last may be in contravention of clauses 19 and 20 of 45 and 46 Vic. (cap. 56) it has been cancelled, and the allowances (except the reduction in meter rentals) will not become operative.

Cork.—For some time past the Electric Lighting Committee have been considering the subject of the introduction of the electric light, but before they proceed further they wish to obtain the advice of an electrical expert. A special meeting of the Committee will be held on the 27th prox., when the notices of intention to apply for Provisional Orders given by the Cork Gas Consumers Company, the Cork Electric Light and Power Company, and the Electricity Supply Corporation of Ireland, will be discussed. At this meeting the question of the expediency of the Corporation applying for a Provisional Order will also be considered.

Denbigh.—At the last meeting of the Town Council the Mayor reported that the Manchester Edison-Swan Company had laid before him certain terms and conditions upon which they were willing to introduce the electric light into the town, and on the motion of Mr. Mellard the subject was referred to the Lighting Committee for consideration and report.

Douglas (Isle of Man).—In consequence of the enormous traffic between Douglas and Kirk Braddon, a number of influential local gentlemen have been considering the advisability of constructing a tramway between the two places. The proposers of the scheme have received a report from a firm of consulting engineers on the subject, and are assured that no difficulty stands in the way of the working of either an electric, cable, or horse tram service.

Dover.—The new school of science, art and technology, which has been erected by the Dover Corporation at a cost of £10,000, was opened on the 19th inst. The school is lighted throughout by electricity.

Dublin.—Several of the Directors and officials of the Dublin United Tramways Company have left for the United States to study the various systems of electric traction in that country with a view to introducing the best system of electric traction on the city tramways.

Edinburgh.—The Town Council have decided to extend their electric light mains to East London-street by way of Broughton-street, at a probable cost of £550. The question of introducing the electric light in Grassmarket and West Bow was remitted to the Cleansing and Lighting Committee for consideration and report.

Electric Traction in Spain.—An application has been made for a 60-year concession to construct and operate an electric tramway between Cadiz, San Fernando and Chiclana.

Electric Traction on the North Staffordshire Tramways.—A deputation of some 20 gentlemen, including the Mayors of Stoke-on-Trent and Longton, and the representatives of the Hanley and Burslem Town Councils, and other local authorities in the Potteries, is visiting Havre for the purpose of inspecting the system of electric traction adopted by the tramways in that town, with a view to the introduction of the system on the North Staffordshire Tramways, which serve the Potteries.

Enfield.—At the last meeting of the District Council a letter was read from Mr. T. Ellis, of Bycullah Park, stating that he was acting on behalf of a company which is being formed for the purpose of supplying electric current to Enfield, and requesting the Council to support their application to the Board of Trade for a Provisional Order. The Chairman said that if the Council should decide to adopt a refuse destructor scheme it might be advisable for the Council to keep the electric lighting powers in their own hands, and on his suggestion the letter was referred to the General Purposes Committee for consideration and report. In the meantime Mr. Ellis is to be asked to give details of his scheme.

Fire.—It is stated that the electricity pavilion at the Bordeaux Exhibition has been totally destroyed by fire, caused by the explosion of a gas engine.

Fire Prevention.—The United Asbestos Company, Dock House, Billiter-street, E.C., write to say that the serious results arising from such deplorable accidents as that which recently occurred on the s.s. "Iona" might be greatly minimised, or prevented, by covering the partitions and ceilings of the various compartments with asbestos "Salamander" embossed decorations, or lining them with asbestos millboard, or constructing them entirely of specially-prepared asbestos, and thus preventing the fire spreading beyond the compartment where it occurred. These suggestions also apply to buildings, and particularly to warehouses, stores, factories and workshops, where the contents render the chances of fire great.

Glenisla.—A meeting of local influential gentlemen was held at Glenisla last week for the purpose of considering the proposal to construct a light railway from Alyth to Glenisla and Braemar, to decide the gauge of the line and the motive power to be adopted. Mr. Japp said that he thought the proposal a feasible one. It had been estimated in 1881 that the line would cost about £150,000, but the chief question for them to consider was whether, in face of the great progress which electricity had made, they ought not to

Digitized by Google

adopt it as the motive power. Mr. W. S. Barber Starkey, of Knockshandoch, read a letter from a firm of electrical engineers, who stated that there should be no difficulty in introducing the overhead conductor system on a 15-mile light railway, and by employing this system the cost of running should be materially less than by steam locomotives. Resolutions appointing a committee to make the requisite arrangements with the view of promoting the scheme, and pledging the meeting to promote the same, were adopted.

Hampstead (London, N.W.).—At the last meeting of the Vestry the Lighting Committee reported that the Vestry Clerk had taken proceedings against the London and Hampstead Battery Company for non-compliance with the London County Council's bye-laws, under the London Overhead Wires Act, with reference to the wires placed by them over and along the streets of the parish. The Company, however, undertook to comply with the bye-laws, and on this condition the summons was withdrawn. The Committee also reported that they had authorised their engineer to expend £2,343 in providing additional machinery for the electricity station. The engineer has also been empowered to order certain materials, including a number of house service boxes at 35s. each. The Vestry have hitherto paid £3. 16s. each for these boxes. The Committee further reported that they had given instructions that no pupils or improvers were to be employed at the electricity station in future, and that they had insured their entire staff against accident, the insurance covering injuries arising from electric shock. The report was approved, and instructions were given to obtain an electric motor for driving the chaff-cutting machine at the stone-yard at a cost of £24. 3s. 9d., and, on the motion of Major-Gen. Young, it was also decided to fix a Blackman electrically-propelled ventilating fan in the Board room.

Hastings.—The following letter from Mr. L. Andrews, Managing Engineer of the Hastings Electric Light Company, appears in the *Hastings Times* of the 21st inst. :—

Sir: We saw in the report of the Hastings Gas Company, published in your issue of the 7th inst., that Dr. Gray is said to have stated that for electricity to compare favourably with gas it must be reduced in price to 3d. per unit. Although we have never actually tested the light-giving properties of Hastings gas as compared with electric light, we had always understood from experiments that had been made in other towns that, with gas at 3s. per 1,000 cubic ft. and electric light at 6d. per unit, the total cost for a given amount of light would be practically the same. In order to see which of these statements was correct, we have had fitted up at the works seven Bray gas burners on one side of a room, and a 200 c.p. Ediswan electric lamp on the other side. By means of a Bunsen grease spot photometer the light was adjusted until it was equal from each source. These were left burning for two hours, from 9 p.m. to 11 p.m., and careful measurements taken of the gas and electricity consumed. It was found that 142·2 cubic ft. of gas had been used—this at 3s. per 1,000 cubic ft. is about 5d., whereas the electricity meter showed that only 0·76 units had been used. In order to bring the total cost up to the same as that of the gas it will be necessary to reckon the electricity at 6½d. per unit instead of 3d., as stated in the gas report. Dr. Gray will be interested to know that several of our customers will not pay on an average more than 6d. per unit for their current used during this half-year, whereas many, profiting by our new system of charging, are replacing gas lamps with electric lamps, for which they will not pay more than 4d. per unit for the current used. From this it is obvious that in many cases it will be necessary for the Gas Company to further reduce the price of gas to 2s. per 1,000 cubic ft. before they can compare favourably with the present price of electricity. We shall be pleased to repeat the above experiments in the presence of Dr. Gray, or any others whom they may interest.—Yours faithfully, L. Andrews.

As the *Hastings Times* remarks, "but for the cost of electric light wiring the Gas Company would soon be brought to reason."

Huddersfield.—A sub-committee has been appointed to consider the subject of letting out electric motors and heating and cooking appliances on hire, together with the prices to be charged therefor.

Hull.—Mr. Rienzi Walton will hold a Local Government Board on Thursday next, into the application of the Town Council for sanction to borrow £8,000 for electric lighting extensions.——The Electric Lighting Committee have received 57 applications for the position of borough electrical engineer. The Sub-Committee are to select 3 names for submitting to the Council, in whose hands the final appointment rests.

Killarney.—The public auditor (Mr. J. Calvert) recently held an audit of the accounts of the Town Commissioners. The decision as to the legality of the payments made by the Commissioners for gas and electric lighting was reserved for six weeks.

Leicester.—The accounts just presented to the Corporation by the Gas and Electric Lighting Committee show that the result of the last half-year's working is a loss of £951. 14s., after allowing for £588 appropriated for sinking fund purposes and £268. 3s. 1d. profit on the electric light fitting department. The total loss for the year is £1,142. 10s. 6d. At the last meeting of the Town Council a memorial from the local electric light wiring contractors against the competition of the Electric Lighting Committee in connection with electric light fitting, was presented. The memorialists urged that the competition threatened to overwhelm their business and was stifling that healthy trade competition which would otherwise exist for the benefit of the public. They further prayed that the Committee might be instructed to refrain from such competition in future. The petition was referred to the Committee for consideration and report.

Liverpool.—The Liverpool Electric Supply Company (Limited) agree to postpone the completion of the purchase of their undertaking on condition that the same is completed within six weeks from the date of the Act of Parliament authorising the purchase, and providing the Act is passed next year.

Nottingham.—On the invitation of Sir John Turney (Chairman of the Electric Lighting Committee), several members and officials of the Corporation attended at the electricity station on Friday last to hear an account of the progress made by the electric light during the first year of working. Sir John stated that their total capital expenditure to date amounted to £48,633. The complete figures for the year were not yet available, but their receipts for the first nine months amounted to £2,090. 18s. 9d. The cost of generating the current had been £1,383. 16s. 4d., leaving a gross profit of £707. 2s. 5d. £1,355 had been set aside for interest, sinking fund, &c., and thus there was an actual deficiency of £647. 17s. 7d. for the nine months, but he believed that when the figures for the last quarter of the year were forthcoming it would be found that there would have been no deficiency. He also said there had not been the slightest hitch or breakdown during the year, and that the demand for current was increasing in a most satisfactory manner; they were at present supplying electric current to an equivalent of 13,547 8 c.p. lamps, and he had no doubt that next year they would be able to show a fair profit. They had already laid 12 miles of cables, and he anticipated that they would lay down as many more during the ensuing year. The Mayor complimented Sir John Turney on the result of his labours, and presented him with a gold key as a memento of the work. In returning thanks Sir John compared the progress made in this country in electric traction and in the United States, and trusted that they would shortly have electric tramways in the town.

Oldham.—At the last meeting of the Electric Lighting Committee the borough electrical engineer (Mr. S. Wilmott Newington) stated that 261 additional lamps had been connected to the mains during the month, and that they had now practically reached the limit of the capacity of their present plant. It was also decided to reduce the meter rent to 10 per cent. on the cost of the meters.

Telegraphic Delays.—At a specially-convened meeting of the Home Affairs Committee of the Glasgow Chamber of Commerce on Monday, the question of the alleged insufficient telegraphic communication between Glasgow and London was discussed, and it was unanimously agreed to make strong representation to the Postmaster-General to provide adequate and increased telegraphic facilities. A memorial to this effect will be at once presented.

Telegraphic Extensions in Japan.—The Japanese Government has ordered 800 miles of submarine cable from the Telegraph Construction and Maintenance Company. It is understood that this is intended for effecting telegraphic communication between Japan and Formosa. The Japanese have determined to lay this cable themselves, and it will be shipped to them in sealed tanks by chartered ships. As reported recently in our columns, the Japanese Government are having a cable ship built at the shipbuilding yards of Messrs. Lobnitz and Co., of Renfrew. This ship will be fitted with the most modern cable-laying gear by Messrs. Johnson and Phillips, so that the Japanese will shortly be able to lay and repair their own cables.

Theatre and Music Hall Lighting.—The New County Theatre, Reading, is lighted throughout by electricity.——The Empire Palace Music Hall, Sheffield, at present in course of erection, will also be lighted electrically. Current will be obtained from the Sheffield Electric Light and Power Company.

Tipton.—At the last meeting of the District Council a letter was read from the Board of Trade in reply to a communication from the South Staffordshire Tramways Company as to the introduction of an improved system of traction on their lines. The Board stated that they were unable to regard as satisfactory the circumstances under which the Company's application for a further renewal of the authority to use steam on a portion of their lines was made. They had frequently sanctioned the use of steam, notwithstanding the objections of local and road authorities, in the hope and assurance that an improved system of traction would be introduced within a reasonable period. The Company had made little progress in this direction, and were unable to show that there was any definite prospect of any possible arrangements in this respect. Under these circumstances the Board doubted whether they were justified in granting any further extension, but having regard to the consensus of local opinion, that it would be detrimental to the public if the tramway ceased to work, they had decided to give a final opportunity to the Company of providing a proper system of traction. They therefore enclosed an order for authority to use steam until

Digitized by Google

the end of the year. No application for a further extension would be considered unless the Company were able to satisfy the Board that arrangements for improved traction were actually in progress, or the local and road authorities supported the application, giving adequate reasons therefor. The subject was debated at some length by the members of the Council, and finally a motion that the Council object to the Company using steam power after the expiry of the extension allowed by the Board of Trade, was passed.

TUNBRIDGE WELLS.—Major-Gen. C. Phipps Carey held a Local Government inquiry at the Town Hall on Tuesday into the Council's application for power to borrow a further sum of £12,000 for electric light extensions. It was stated that the electric lighting scheme had proved a great success, no fewer than 3,500 lights having been applied for. Mr. Preece gave details of the proposed extensions, and there was no opposition to the loan.——The Town Hall was lighted by electricity for the first time on the 19th instant. The electricity works will be formally opened early next month by Lady Salomons.

COMPANIES' MEETINGS AND REPORTS.

Brush Electrical Engineering Company (Limited).

The sixth annual general meeting of this Company was held at the Cannon-street Hotel on Monday, under the presidency of Mr. J. B. Braithwaite, jun.

The SECRETARY (Mr. Broadhurst) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Before moving the adoption of the report and accounts it will be my pleasure to make a few remarks upon the balance sheet, the profit and loss account, and upon the general prospects of the Company. Taking first the balance sheet, and looking at the debit side of it, you will see that there has been no change during the year in the amount of the capital of the Company, which still remains at £450,000 of share capital and £125,000 of Debenture stock. The creditors have been reduced during the year from £72,324 to £44,888, showing a reduction of about £27,000. The loans and overdrafts from bankers have increased from £25,000 to £78,000. Provision for depreciation on property, patents and goodwill account remains as last year, and the items of profit and loss account, which follow, are fully dealt with in the report. The contingent liability in respect of uncalled capital has been reduced from £39,697 to £5,547, so practically it disappears, because the £5,547 remaining is not likely to be called up. On the credit side the item of property, patents and goodwill has been increased by additions to plant during the year by £2,487, and, after deducting the usual sum for amortisation of lease of the Borough-road premises, stands at £238,374. Stock in hand stands at £100,800, and the item of debtors stands at £141,400. Cash at call, at bankers and in hand, amounts to £3,910. Shares and debentures with other companies at cost, less amounts written off, amount to £61,236. Liquidators' balances and suspense accounts is an item standing at £1,963, and the balance of foreign and colonial branches accounts stands at £104,305. The chief item probably which will attract your attention in this balance sheet is the increase of the loan from bankers from £25,000 to £78,000. That has arisen from the two items to which I will call your attention. £27,000 of it is the result of reducing the amount due to our creditors from £72,000 to £44,888, and the remaining amount is due to the increase of our shares and debentures in other companies. It practically represents the difference between the £39,697 liability on shares we had last year and the £5,547 which we now have. Those calls have all been paid up during the year, and it is those items which account for the increase of our loans from the bankers. I will just turn to the profit and loss account for a moment, and there you will see that the gross profit for this year has been £37,853, being, as we have mentioned in the report, a decrease of close upon £20,000 from the figures of last year. That amount, as we have already mentioned in the report, is due entirely to the difficulties which have occurred in connection with our contract with the City of London Electric Lighting Company, to which I will refer more particularly later on. On the other hand, the general charges stand at £17,027, against £19,974 last year. The maintenance of buildings and plant has cost £2,708, and you will observe at the foot of the page the certificate of our engineer that the buildings and plant under his supervision have been maintained in an efficient condition during the year ended June 30, 1895. There is no other item of interest, I think, in the profit and loss account except the amount of bank interest and commission, £2,227, which will disappear on the issue of the additional amount of Debenture stock which we are now proposing to make. Now, with respect to this issue of Debenture stock, I stated last year that the loan of £25,000 from the bank was likely to be only a temporary matter, and that, therefore, it was not worth while to issue additional capital to liquidate it. All that I said last year with respect to that matter applies with equal force to the amount we now owe our bankers of £78,000, and for that reason we do not propose to make any permanent addition to the capital of the Company. I think you will see from the figures I am going to give you that it would be unwise to saddle ourselves permanently with additional capital, and we propose to issue this amount of £105,000 as Redeemable Second Debenture stock. On the other side of our balance sheet we have assets more or less liquid which might come in in the form of cash—shares £61,000, balance of debtors over creditors £96,000, and stock £100,000, making a total of £257,000. Of course, I hope we shall not see anything like the whole of that sum come in in cash, because if we did realise the whole of our stock, and the whole of the difference between our debtors and creditors, it would mean that our business had practically come to an end; but at the same time the balance of debtors over creditors is very much larger than it would be in a normal year's trading, owing to the fact I mentioned last year of the heavy retention funds which are kept in connection with some of our municipal contracts. I think it is easy to suppose, however, that the £96,000 might be reduced to £50,000, and in that way we should get in about £50,000. That, in addition to the shares and debentures which are constantly in course of realisation, would give us sufficient to redeem the whole of this £105,000 which we propose to issue. In view, therefore, of the undesirability of burdening the Company with any issue of capital which we should have no power to redeem in the future, we propose to make the new Debenture stock redeemable at 105 per cent. at any time on six months' notice. That being so, I think you will agree that it is wise to make this issue so as to pay off our bankers and give us that amount of cash in hand which a company of our standing ought to possess. At the same time it is more than probable, unless some very unexpected expansion of our business takes place, that in the course of the next two or three years the whole or a considerable portion of that Debenture stock will be redeemed. There is one other matter connected with the balance sheet to which I ought to refer—that is, the position of the Preference shareholders. You will see from the report that we are of opinion that the Preference shareholders are entitled to the whole of the profit made during the past year up to an amount sufficient to pay their full dividend. The net profits are, unfortunately, not sufficient to pay the full dividend of 6 per cent. on the Preference shares, but they are sufficient to allow of the division of a sum of a little over £2,000, and that distribution we propose to make among them at the earliest possible date. Under our Articles of Association the Preference shares are cumulative as regards the year, but not as regards subsequent years. I mean that they are a first charge over the Ordinary shares to the extent of their full dividend on the profits of the year, but they are not cumulative from one year to another year. During this year we have earned £7,541, out of which they have received £5,400, so that another sum of about £2,000 is due to the Preference shareholders, which I hope they will receive next year in addition to their ordinary 6 per cent. I do not know that there is any other item in the balance sheet or profit and loss account specially calling for notice. I will therefore turn to other matters connected with the Company, and, of course, the first question you will want to hear about is the circumstances in connection with the contract with the City of London Electric Lighting Company which have turned what would have been the best year in the Company's existence into the worst, unfortunately. That only illustrates the disadvantages in some ways of having contracts of such very great magnitude, but it may be a satisfaction to the shareholders to know that apart from the City of London Electric Lighting Company's contract, the past year has been the best in the history of the Company. We have made more profit than we ever made before apart from that one contract. It is due to the shareholders to know that, as otherwise they might consider this large drop in the profits as due to a falling-off of our business generally, or to our not being able to conduct the business at a profit. That, however, is no the case, the decrease being entirely owing to extraordinary circumstances connected with the City of London Electric Company's contract I do not know that it is for me to go into detail about it (cries of Yes). I do not think I am at liberty to go into exact details; but I think I can give you in general terms sufficient information to understand the position. The contract with the City of London Electric Lighting Company was one of considerable magnitude, amounting to something like £300,000, and under that contract the decision of all points connected with it was left absolutely to the engineer of the City of London Electric Lighting Company for the time being. That is a usual provision, and would have been satisfactory under ordinary circumstances; but we have been unfortunate enough to have no fewer than three engineers to deal with during that contract, each of whom has become practically supreme judge as to whether the contract was being carried out to his satisfaction. I need not tell you that among electrical engineers each has his particular views, so you will understand that the change of engineers, which took place in the City of London Company in December of last year, was a very unfortunate thing for us when it turned out that the new engineer had very different views of what the obligations under the contract were from those of his predecessor. We have done the very best under the difficult circumstances in which we were placed. In view of the fact that the engineer of the City of London Company is made supreme judge, there was practically no alternative for us but to accept the altered view of what were the obligations under the contract or to resort to an expensive or ruinous lawsuit. I do hope that you will give us credit for making the best arrangements we could under the circumstances, although the result has been to have a serious effect on our profits for the past year. We have tried to adjust matters with the new engineer of the City of London Company on the basis he wished, and that has been accomplished, and work under the contract is again proceeding. With respect to the general business of the Company, we are in the fortunate position of having our works fully occupied with orders for some months in advance. During the year we have carried out and opened central stations for electric lighting for the municipalities of Worcester and Leicester; and we have also opened for the County of London and Brush Provincial Company a station for the supply of Dover. All these have turned out entirely satisfactory, and we have work of a similar character in hand for St. Luke's, for Clerkenwell, and for the Wandsworth district for the County of London and Brush Provincial Company and various other stations up and down the country. As regards our electrical shops, therefore, we have plenty of work in hand; and with respect to our car shops we are also full of orders at the present time. We have been building locomotives for the Beira Railway, which is being constructed for the opening up of South Africa; and we have also in hand a large number of cars for the Rouen Tramways Company, which

Digitized by Google

has been equipped with electricity. Then, with respect to the engine-building side of our works, we have carried out a considerable number of orders. As you will see from the report, we have already sold about 35,000 H.P. of engines, and our chief engineer, Mr. Raworth, has just introduced a new enclosed high-speed engine, from which we hope great things in the future. This is an engine which will be equally suited for electrical work and all other kinds of work to which steam engines are generally put, and we hope it will bring considerable additional orders into our engine shop, and give us an engine which we can manufacture at a very satisfactory profit. That is our chief duty to our shareholders after all—to find articles which we can manufacture, in the present severe state of competition, at a reasonable profit. We believe that will be the case in this instance. The question of electric traction is occupying our attention very much, and we must all feel—we who read the daily newspapers, and know what is going on with respect to electric traction—that that is the thing we must look to very largely in the future to keep our electrical engine shops full in this country. Up to the present time electric traction in Great Britain has been practically a dead letter. If, however, you go to the United States of America, to Canada, or many other places, you will find quite small villages have their electric tramways and railways. I suppose that in the States there are now thousands of miles of tramways worked by electricity, whereas in this country the electrical tramways now opened can be counted on the fingers of one hand. At the same time, the thin end of the wedge has been introduced in this country, and no doubt when the three or four tramway works now in course of construction are opened, and the public realise the immense convenience and acceleration of travelling which are due to the adoption of electricity for working the tramways, we shall see, I believe, a very great rush of electrical tramway business in this country. With regard to the working of railways by electricity, we have in England two systems worked entirely by electricity—the City and South London Railway, running out to Stockwell, and the Liverpool Overhead Railway, both of which are working satisfactorily. There are two other important railways in course of construction under our streets. One is the Waterloo and City line, and the other the Central London Railway, which will run from the City up to Shepherd's Bush, through Holborn and Oxford-street; therefore, even in this country, electric traction is taking hold, and when we read in the American papers the accounts of the first locomotive that has been built for handling main-line traffic, I think we must see the great possibilities there are for electric traction. The first locomotive turned out for the Baltimore and Ohio Railroad Company has drawn a freight train weighing 1,200 tons at 15 miles an hour, and on a speed test is reported the other day to have attained a speed of 61 miles an hour without any difficulty. I think we may see, therefore, that the electrical industry has an enormous future before it in the direction of electric traction. As regards electric lighting, that is not likely to retrograde; but electric traction is in this country comparatively a new field, and I look in this direction for a very large amount of business in the future. I do not think there is any other matter to which I need call attention except this—that in view of the position in which the Company is placed by these unprecedented circumstances with regard to the City of London Electric Lighting Company's contract, my colleagues and myself feel that it would be the right thing for us in the ensuing year to forego half our fees. That, I think, will indicate our desire to do our best for the Company in every way; and we therefore propose for the ensuing year to take only half the fees to which we are entitled under the Articles of Association. I shall be exceedingly happy, after the adoption of the report has been seconded, to answer any questions I rightly can, and give any information which I have failed to impart in the remarks I have already made (applause).

Mr. B. H. VAN TROMP: I have much pleasure in seconding the motion.

The CHAIRMAN: The motion is—

"That the report of the Directors and statement of accounts to June 30, 1895, now presented to the shareholders, be received, and that the same be hereby adopted."

Mr. WARD desired to know whether the Chairman and the Directors endorsed the statement in the auditors' certificate, that the shares and debentures in other companies held by this Company were "of the full value stated in the accounts." It was of considerable moment to the shareholders to know whether the shares, represented at £61,000, were of that value or anything approaching it. He regarded the present report as the most unsatisfactory that had ever been issued to the shareholders. With a trading company one naturally expected every now and then to have losses; one year they would make a large profit, but in another year they would have a loss. In their own case the loss which had been sustained had not been in ordinary trade matters, and he could not help thinking that the Directors made a considerable blunder in agreeing that in the event of any difference arising in connection with the contract with the City of London Company the matter should be referred to the engineer of that Company, for which they were doing the work. He had never heard of such an arrangement. Usually each party appointed an umpire, and in the event of any difference arising another umpire was appointed to settle it. Although one was glad to hear from the Chairman that they had entered into various other contracts, one was anxious to know whether they contained some stipulation similar to that in the contract with the City of London Company. He hoped the Directors would be very careful in the future in seeing how the contracts were drawn up and signed. He had been very glad to hear the Chairman say that the Directors would next year forego half their fees.

Mr. LAMONT asked if the Chairman could throw any light on the fact that for two or three weeks before the issue of the Directors' report the shares were going down.

Mr. McLEAN asked how it was that, while enough profit had not been made to supply the Preference shareholders with their dividend, £6,750 had been divided among the Ordinary shareholders for the first six months of the year. He wished to know if the item of £5,385 standing on the debit side of the balance sheet against provision for depreciation on property, patents and goodwill account, was for the present year, or was a standing account, or if any portion of it was for the present year.

The CHAIRMAN: With regard to the question which was put by Mr. Ward, I think, with reference to the shares and debentures we hold in other companies, that is a matter which, as he says, is a very important one naturally, to the stability of the balance sheet, and it is a matter to which we have given very great attention, as have also the auditors. Rather more than half of the amount—something like £35,000 out of the £61,000—are shares quoted on the London Stock Exchange; and with respect to those I may say that, personally, I shall be considerably disappointed if when we realise them we do not make a substantial profit of £3,000 or £4,000 on their sale. With respect to the remainder—say £25,000—they are shares and debentures mostly in connection with undertakings in which we have been interested in the past. I think I may say that in every case those undertakings are in an improving position, and in many cases we are in receipt of dividends from them. In the case of similar undertakings, which stood in our books for some time past, we have sold the shares in the past year, and realised a satisfactory profit on the transaction. Some of these shares are valuable to us apart from their actual market value, as they give us a controlling interest in companies which supply us with orders. Answering Mr. Ward's question, I think I may say that after anxious consideration about it, the Board believe that they are well worth the figure standing in the balance-sheet. With reference to the conditions in the contract with the City of London Company, I was not responsible for negotiating that contract; that was in the days before I was Chairman of the Company. At the same time, I think it very probable that I should have done the same thing had I been in the position of our then manager, as it was impossible, I think, to foresee that there would be three new engineers of the City of London Company in as many years; and the circumstances are so extraordinary and unprecedented that I do not think any reasonable amount of foresight exercised four or five years ago could have avoided the difficulties in question. At the same time, I quite agree that it is a most unsatisfactory form in which these contracts are drawn up, but it is the usual form. If we did not take the contracts on these terms our competitors would do so; and I am not sure that it would not be well if they did do so in some cases. I may, however, say, with reference to the other contracts in hand, that we have no indication at present of any difficulties arising similar to those connected with the City of London Company. Our manager tells me that we have carried out a number of similar contracts without any difficulty, but in those cases we did not have changes in the engineers. That has been the real difficulty. A gentleman remarked very properly on a fact that has given extreme annoyance to the managers and the Board, and to myself particularly, of there having been some leaking out of the purport of our report. We are investigating this matter, but so far we have been unable to trace anything. It is very annoying to those who are connected with the conduct of the Company, as it would seem that "those in the know" have been taking steps to realise at better prices than they could have done after the issue of the report. I do not think I need assure the shareholders that neither my colleagues nor myself have done anything in this direction. All that I have done has been to increase my holding on the drop which took place in the shares, which have fallen, I believe, to very much below their intrinsic value. With regard to the question of Mr. McLean, with reference to the interim dividend, the shareholders will realise from what I have said, and from the report, that at the time we paid the last interim dividend, everything was proceeding entirely satisfactorily with us. We had a most careful balance sheet and statement prepared, showing that an interim dividend both on the Preferred and the Ordinary shares had been fully earned, and under these circumstances, following the practice of previous years, we thought it right to pay it. The whole of the loss has been in the second half of the year, and has been owing entirely to the extraordinary claim put forward by the new engineer of the City of London Company. I imagine it will be the view of the shareholders in the future that we should not pay any interim dividend on the Ordinary shares, although we shall, unless you instruct us to the contrary, pay an interim dividend on the Preference shares if the circumstances warrant it. Probably as regards the Ordinary shares, it will be better to wait for the completion of the year. Unless any gentleman has any other remark to make or question to ask, I will now put the motion.

A SHAREHOLDER inquired how much longer the contract with the City of London Company had to run.

The CHAIRMAN: There is no definite period named for the completion of the contract with the City of London Company. That Company are bound to order from us their plant for the supply of the western and central districts of the City, but there is no period within which they are bound to give us those orders.

Mr. WARD: We have representatives on the Board of the City of London Company.

The CHAIRMAN: We have none at present. We had two—the late Duke of Marlborough, who was then Chairman of this Company—and myself. On the Duke's sudden death no effort was made by the City of London Company to replace him. That left me alone to represent this Company on that Board, from which I have felt it my duty to withdraw, not specially in connection with our contract, although I think we have been badly treated by them in that matter, but because I dissent from the policy their present engineer is carrying out in the interests of the City of London Company itself.

Mr. McLEAN asked what proportion of the sum set against depreciation on the debit side of the balance sheet had been set aside this year.

The CHAIRMAN: That is the same amount as stood there last year. He then put the resolution, and declared it carried *nem. con.*

Digitized by Google

On the motion of Mr. VAN TROMP, seconded by Mr. GEORGE RICHARDSON, a shareholder, Mr. Edward Woods and Mr. A. Ayres, the retiring Directors, were re-elected to their seats at the Board; and the auditors, Messrs. Cooper Brothers, were also reappointed.

In answer to a question by Mr. LAMONT as to Mr. Raworth's high-speed engine,

The CHAIRMAN said: Under our agreements all patents taken out by our officers are offered to the Company first, and we pay nothing for them. All the payments made are by way of royalty on the sales.

Mr. FRY proposed a vote of thanks to the Chairman and Directors. They would not, he pointed out, meet in the ordinary course for another twelvemonth; but could not the Directors in some way meet them or send out a circular at the end of the half-year—next January or February—and give them some information as to the position of the Company?

The motion having been seconded and agreed to,

The CHAIRMAN said: It is not usual to hold a meeting unless you can present accounts, and in a company like ours that would mean an interruption of our factories for two or three weeks, which would be very serious if repeated more than once a year. As to sending out a circular to the shareholders when we have anything important to communicate, it is a valuable suggestion, and if we can do so at the end of the six months we will do so. We are very much obliged to you for your vote of thanks, which is greatly appreciated at a time like this.

The proceedings then terminated.

Halifax and Bermudas Cable Company (Limited).

The sixth annual general meeting of the shareholders of this Company was held on Tuesday last, at the offices of the Company, 33, Old Broad-street, London, E.C. The Directors' report and accounts for the year ended June 30, 1895, were unanimously adopted, and the retiring Directors (Messrs. Thomas Skinner and T. G. H. Glynn), as well as the auditors (Messrs. Gribbon and Holroyd), were re-elected.

The Directors' report states that the cable receipts for the past year amounted to £4,203. 7s. 10d., as compared with £3,462. 17s. 7d. for the previous year. This increase is attributed to the improvement in the general business condition of the Bermudas. As a result of the year's working there is a profit of £1,023. 9s. 8d., as compared with £328. 16s. 4d. for 1893-94, this reducing the debit to capital to £3,870. 5s. 4d.

The report also states that the Company's cable has worked with complete efficiency throughout the year, and its electrical condition continues excellent.

The Directors also report that they have obtained the assent of all the holders of the Company's debentures to such a modification of the Trust Deed as permits of the application of the sinking fund to purchases or drawings. Accordingly offers for the sale of debentures to the Trustees were invited in June last, when £11,200 of the Four and a-Half per Cent. First Mortgage Debentures were acquired and cancelled at a cost of £10,216. It is intended to apply the sinking fund half-yearly, viz., in June and December. The reduction of the capital outstanding, resulting from this operation, permits of the extinguishing of the debit to capital account of £3,870. 5s. 4d., and the writing down of the capital expenditure by £7,329. 14s. 8d.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c., &c.*

CRYSTAL ELECTRIC LAMP COMPANY (LIMITED).—This Company was registered on September 17th with a capital of £15,000, in £5 shares, to enter into an agreement with James W. Rogers, electrician, of Highgate, London, N., to carry on the business of an electric light company in all or any of its branches, and to carry on business as electricians, electrical and mechanical engineers, manufacturers of and dealers in electric lamps and electrical apparatus and appliances. The subscribers, with one share each, are: James W. Rogers, F. Naylor, H. J. Gibbs, J. Wiggins, J. H. Smeed, W. W. Smith, and G. Hawkins. The first Directors are James W. Rogers, H. J. Gibbs and F. Naylor.

LANCASTER AND TONGE (LIMITED).—This Company was registered on September 17th with a capital of £30,000, in 50 £5 per cent. Preference shares of £100 each and 250 Ordinary shares of similar value, to acquire and carry on the business of an engineer, metal founder, millwright, boiler maker, &c., now carried on by R. F. C. Tonge under the style of "Lancaster and Tonge," Pendleton, Lancs.

LITHANODE ELECTRIC STORAGE COMPANY (LIMITED).—This Company was registered on September 23rd with a capital of £12,000, in £1 shares, to acquire and take over as a going concern the business carried on by the Lithanode and General Electric Lighting Company (Limited) (in liquidation), at Millbank-street, London, S.W., to enter into agreements with the said Lithanode and General Electric Lighting Company (Limited) and its liquidator, and with J. T. Niblett, and to carry on the business of electricians, mechanical and electrical engineers, electrical instrument makers, lamp manufacturers, manufacturing chemists, contractors for public and private works, and the general business of an electric, gas and other light company in all or any of its branches. The subscribers, with one share each, are: E. G. Dakin, J. H. Matthews, F. Stuttaford, R. A. Dawson, W. J. Cooling, H. W. Roach, W. R. Elston.

ROUND'S ACCUMULATOR COMPANY (LIMITED).—This Company was registered on September 17th with a capital of £10,000, in £1 shares, to enter into a proposed agreement between Benjamin Round and E. Lester, W Topham and J. Hancock, to generate, accumulate, distribute and supply electricity, compressed air or any other force or power; to construct, lay down, establish, fix and carry out all necessary accumulators, cables, wires, lines, lamps and works, and to carry on the business of electricians, electrical contractors, mechanical engineers, and manufacturers and suppliers of and dealers in electricity and compressed air. The subscribers, with one share each, are: J. Leah, engineer; W. J. Warrilow, J. K. Frost, J. Stafford, A. Woolmer, M. Round, and F. P. Burt.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30$\frac{3}{16}$d. per oz. (Sept. 26th). Consols (2$\frac{3}{4}$ per cent.) 107$\frac{11}{16}$—107$\frac{13}{16}$ for money, 107$\frac{3}{4}$—107$\frac{7}{8}$ for account (Sept. 26th); 2$\frac{1}{2}$ per cent. 106$\frac{1}{8}$—106$\frac{3}{8}$. Stock Exchange Settling Days: Consols, Oct. 1st; Stocks and Shares Continuation Day, Oct. 14th; Ticket Day, Oct. 15th; Pay Day, Oct. 16th; Mining Shares Carry-over Day, Oct. 12th.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—At the last general meeting of this Company resolutions were passed increasing the capital of the Company by £100,000, divided into 20,000 shares of £5 each. The Directors now offer 10,000 of these shares for subscription. The new capital is to be issued at a premium of 5s. a share, and will in the first instance be offered to the present shareholders in the proportion of one new share for every two existing shares.

BUDAPEST TRAMWAY COMPANY.—To meet the expenses in connection with the conversion of their horse tramways into electric tramways, for which the concession was received some time ago, the Company is about to increase their original share capital of 3½ million florins by 2 million florins (£200,000).

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended September 22nd were £831, against £835 in the corresponding week of 1894, a decrease of £4. The total receipts for half-year amount to £10,148, against £10,238 for the corresponding period of 1894, a decrease of £90.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—We are informed that Mr. Joseph Bevan Braithwaite, jun., has resigned his seat on the Board of Directors of this Company.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 22nd inst. amounted to £1,239. The amount for the corresponding week last year was £955; increase, £284.

RAND CENTRAL ORE REDUCTION COMPANY (LIMITED).—The annual meeting of this Company was held on Monday last when the directors' report and accounts were passed. The Directors' report states that during the year 357,000 tons of ore were treated, at an average cost of £3. 10s. 5d. per ton, and the actual extraction of gold was 71·6 per cent. The total expenditure for the year, including £45,224 on new works, buildings, and plant, and £1,899 for experimental work, was £90,197, while the receipts amounted to £85,722. The Company has acquired a half-interest in the Siemens and Halske patent for the precipitation of gold by electricity. The Directors express their satisfaction at the progress made with this process during the year, and state that the economy and general advantages of the process are daily making themselves felt. The Managing Director's report also speaks highly of the process, and a list of companies who have adopted or have decided to adopt the process is given. Dividends of 25 per cent. on the Ordinary and £6 per share on the Founders' shares were declared.

SOUTH AFRICAN TERRITORIES (LIMITED).—During the week this Company issued a prospectus inviting applications for £75,000 Six per Cent. First Mortgage Debentures of £50 each. The prospectus states that the Company have acquired the right to construct a railway or tramway from Lüderitz or Angra Pequena Bay to the interior of the Company's possessions, with the option of constructing branch lines, and the exclusive right for a period of 50 years to construct railways in any part of the Company's territories. The lists opened on Tuesday and closed on the same day for town, and on Wednesday for the country.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.—The traffic returns of this Company for the week ended September 20th were £606, an increase of £19, as compared with the corresponding week last year.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow the following securities to be quoted in the Official List: Further issue of 3,498 Seven per Cent. Cumulative Preference shares (Nos. 12,846 to 16,343) of the Electric Construction Company (Limited), and the further issue of 3,163 Ordinary shares (Nos. 1 to 601, 1,092 to 1,181 and 7,529 to 10,000) in W. T. Henley's Telegraph Works Company (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 20th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,972.

WILLANS AND ROBINSON (LIMITED).—The registers of transfers and members of this Company will be closed from 24th inst. to 8th prox. inclusive.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 907. [No. 23. Vol. XXXV.] FRIDAY, OCTOBER 4, 1895. PRICE SIXPENCE.

NOTES.

THE half-yearly report of Willans and Robinson (Limited) should prove very pleasant reading to the shareholders of this prosperous concern. A 7 per cent. dividend is not exactly calculated to make the lucky recipients thereof over curious as to the way in which it has been balance-sheeted. In this instance, however, inquisitiveness would not end in disillusionment. The profit and loss account, it is true, shows that some 17 per cent., or over £3,600, out of a total income of £21,283 has been derived from the sale of licences to foreigners —a source of revenue not likely in the nature of things to prove perennial—but as the greater portion of this receipt has been devoted to increasing the reserve and depreciation funds no exception can be taken. Moreover, it must be remembered that the income derived from foreign royalties may be expected to grow. By this time next year some of the rival high-speed enclosed engines will, no doubt, have got to work, and we shall be interested to see whether competition will have a bracing or a depressing effect on the firm which has so ably and pluckily pioneered this type of engine.

ALTHOUGH the experiments on "The Electrolysis of Milk," which we publish in another column, do not give grounds for supposing that electrical methods of analysis will supplant those ordinarily in use at the present time, still the results are of some interest. The obtaining of a deposit of casein on the sides of the porous partitions farthest from the anode when milk was electrolysed in a vessel divided into three compartments will recall the experiments FARADAY made to prove that a metallic electrode or pole was not necessary to produce chemical decomposition. On the GROTTHUSS hypothesis electrolysis was supposed to be due to a direct attraction exerted by the poles on the opposite constituents of the decomposing compound, which varied as the square or some other power of the distance. But this was disproved by FARADAY ("Experimental Researches," Vol. I., pp. 140-145), who showed that the decomposing forces were the same at all positions between the poles, and that insoluble hydrate of magnesia was produced at the junction between a strong solution of sulphate of magnesia and pure water when a current was passed through. The effect recently observed by M. ANDREOLI is due to the same cause, and he would appear to have found this out, as we are informed that he now connects the sheets of metal in the centre compartment to the negative terminal of the dynamo, whilst the plates in the two outer divisions form the anodes. We further learn that the porous partition may be dispensed with.

WHETHER an electric car is started on the series-parallel system, the motors being placed in series during the early stages and thrown into parallel only when considerable speed has been attained, or whether the less modern rheostat method of starting is adopted, there are many items of expense largely affected by the care which is exercised in making a start. A glance at the instructive set of curves accompanying the article on "How to Start a Car," which will be found in our columns this week, enables one to see what a great difference is made between an easy and a sudden start. And although in the latter case there may be double the maximum power consumed, full speed is not attained in much less time than with a more gradual switching into steady running. Not only does this difference affect the load on the power generators, and the distribution of pressure on the system; but it also touches the question of repairs of motor machinery. A nervous or hasty motorman will sometimes cause a flare that will do more harm to the machinery than months of steady hard work. Indeed, this is one of the chief troubles while working new and unskilled hands into motormen's duties—a novice will be apt to throw the switch hard over to full speed whenever he sees a blue spark; while an old hand is often disposed carelessly to throw the switch over too quickly, rather than be bothered. There is, of course, some difference between the way a start must be made with the series-parallel arrangement, and when rheostats are used; but, in either case, bad starts arise from the same kind of carelessness in handling the switches; and the effect upon the economy of the system may be as marked in the one case as in the other.

IN this country, at any rate until quite recently, the handling of coal within the precincts of an electric supply station was neither a very scientific, methodical nor satisfactory matter. But in recent years, especially where slack and other varieties of small coal have been used, mechanical coal-handling has received greater attention. It is, however, to America that we must turn, if we seek the development of this practice to its fullest extent; for it is by no means an uncommon thing to find, in the electric light and power stations of that enlightened land, the coal being treated to an elaborate

Digitized by Google

miniature Lord Mayor's procession, before it is finally consumed on the firebars of the boiler furnaces. To begin with, in America it is regular practice to put the coal stores at the very top storey of the building, the boilers in the basement, and the engines somewhere between the two. Bucket-and-chain elevators carry the coal skywards from the level of the street, and, at the appointed time, tall shoots convey it downwards to the place where it is to be consumed. In making this double journey, the coal frequently is carried on a very tortuous and complicated route, though we have yet to meet with an instance of its having been conveyed through the company's offices. A variant on this practice is advocated by our esteemed contemporary, the *Electrical Engineer* of New York, and is now in actual operation in the power house of the Toronto Railway Company. The coal is dropped through the bottoms of the trucks on the railway siding, where it falls on to a motor-propelled crusher. It is here crushed to small lumps, and passed into the buckets of conveyor No. 1. Thence it passes under the motor shop and up an incline to conveyor No. 2, by which it is conducted to the storage bins. From these it drops into conveyor No. 8, which lifts it above the boiler house and drops it into a number of spouts, provided with valves, which are so arranged that the coal can be dropped anywhere in the boiler house.

Doubtless our readers have seen mysteriously-worded paragraphs in the daily papers from time to time, especially during the summer, dwelling in an appropriately vague manner on the existence of gold in solution in sea water, schemes for its recovery being at the same time shadowed forth. We are now able to give details concerning at any rate one method. The apparatus is exceedingly simple. plates of iron form the anodes, while the cathodes consist of plates of copper or other suitable material, such as amalgamated zinc, and in some cases a quantity of mercury may be arranged in connection with a cathode, these plates forming, in conjunction with the sea water, an electric battery. The inventor, however, proposes to increase the effect by connecting this apparatus in series with a somewhat more certain and more powerful source of electric supply, such, for instance, as a dynamo. It is claimed that the action of the electric current will deposit upon the copper cathode, or in the mercury, the gold which is contained in the sea water, and which is supposed to be in combination with iodine. Various forms of apparatus are described; for instance, the plates may be attached to a long, narrow float, or hung to a beam trawled from a steamer or sailing vessel, or yet again, the plates may be arranged in a long tube or conduit immersed in a tideway. The chief object to which attention has to be directed is to arrange the apparatus so that the greatest possible volume of sea water is passed through it, and subjected to electrolysis. There is a seductive charm about this idea of a golden haul becoming a common bye-product of summer day's sail, and it is obvious to the meanest comprehension that in this great invention there lies the germ of an undreamt-of development of our mercantile marine. The gold trawling industry will now no longer be confined to members of the London Stock Exchange.

Happy, we are told, is the nation which has no history; and good news is surest when there is no news at all. In the light of these two truths, the shareholders and other persons interested in the Liverpool Overhead Electric Railway may justly claim congratulation. For, while hastening through Liverpool the other day, bent upon crossing to Manxland to see another and a newer electrical railway; and again, while hastening back, we took the opportunity to pay further visits to the useful overhead line and the efficient generating station. We found the cars running the even tenor of their prompt and frequent service; the popularity and usefulness of the line having been enhanced by its extension, in a northerly direction, to Seaforth sands, and in a southerly direction, beyond the furthest dock station, to a populous suburban district. Within the great machinery hall—one of the neatest and most imposing we have ever seen—things were running as smoothly and satisfactorily as were the cars themselves; and we were pleasurably disappointed, so to say, to find that the editorial desire to be told of some interesting "incident" or anxious *mauvais quart d'heure* could not be satisfied.

Tunbridge Wells.—The municipal electric lighting station will be opened in state on Wednesday next, the 9th inst.

University College, Nottingham.—The 1895-96 session commences on Monday next, the 7th inst. Further particulars are given in our advertisement columns.

Cable Interruptions and Repair:—

	Date of Interruption.	Date of Repair.
Aden-Zanzibar	Sept. 2, 1895. ...	Oct. 1, 1895.
Cadiz-Teneriffe	Sept. 25, 1895. ...	—

Long-Distance Telephone Opened.—On September 25th the Berlin-Königsberg telephone line was given over to public use. The charge for conversation of three minutes' duration is one shilling.

Accumulator Traction in Germany.—It is reported that the Hanover Tramways Company has decided to substitute accumulators for the "trolley" on 28 of its electric tramcars. The contract for the accumulators has been given to the Hagen Accumulator Company.

Isle of Man Electric Tramways.—A concession has been granted by the House of Keys for the construction and operation for a term of years of an electric tramway along the Marine Drive, which extends southward from Douglas along the picturesque Manxland coast.

Visual Fog-Signalling at Sea.—The ss. "Calais-Douvres," of the London, Chatham and Dover Railway, has been fitted with an experimental fog-signalling apparatus, consisting of a search light, arranged to throw a vertical parallel beam from forward of the foremost funnel of the vessel.

Central Technical College.—At the recent matriculation examination of the City and Guilds Central Technical College 76 candidates presented themselves, and 62 have been admitted to the College. The highest place was taken by M. Solomon, to whom the Clothworkers' Scholarship of £60 a year and free education has been awarded.

Delineation of Alternate-Current Wave Forms.—A Correction.—In the abstract of Messrs. Barr, Burnie and Rodgers' Paper on "Some New Methods for the Delineation of Alternate-Current Wave Forms," which appeared in our last issue, the authors, by a slip of the pen, on page 721, column two, at the end of line 11, wrote the word "not" in place of the word "most."

Interurban Telephone Tariffs in France.—A notice has just been issued by the French Minister of Commerce and Industry to the effect that on and after January 1st next the charge for the use of the interurban telephonic system of the country between places less than 25 kilometres distant from each other will be reduced from 5d. to 3½d., and in some cases to 2¼d. per three minutes' conversation.

Digitized by Google

Telephone Induction Transmitters.—In connection with the adoption, by the German Post Office, of the Münch induction transmitter, which we described in our issue last week (p. 724), Mr. G. L. Addenbrooke has called our attention to a patent, No. 14,917, dated December 4, 1885, taken out by him in conjunction with Mr. Ferranti. This patent was granted for an induction transmitter in which "the magnetic circuit in the core is completed through metal, or more nearly so than when a straight core is employed." Whereas in the Münch transmitter an iron-wire core is used, in the original apparatus patented by Messrs. Addenbrooke and Ferranti laminations of sheet iron were employed.

Electric Lighting in Shanghai.—The *China Gazette*, in a recent issue, speaking of the growth of electric lighting in Shanghai, says: "A couple of years ago there were only about seven miles of streets lighted by electricity, for which 60 arc lamps were quite sufficient, and there was not a single incandescent lamp in or around Shanghai. Now the electrical department of the Municipal Council runs 140 arc lamps, lighting some 15 miles of streets, and there are about 43 miles of line wire laid, in addition to 6,100 incandescent lamps of 8 c.p. each for domestic purposes. The customers for incandescent lighting have increased from 1 to 55 in number since the Council took over charge of the department."

Toynbee Hall.—The winter session's work at Toynbee Hall was inaugurated on Saturday last by a *conversazione*, which was attended by about 1,200 students. The scientific side of the work at Toynbee was represented by an exhibition of apparatus arranged by the electrical and chemical societies. By permission of Mr. W. H. Preece, C.B., a quantity of telegraphic apparatus (including Morse ink writer, double-plate sounder, single needle, &c.) was available, and the various buildings were in telegraphic communication. The electrophone also connected Toynbee Hall with the principal theatres. On Saturday afternoon, the 5th inst., the Toynbee Electrical Society will visit the Davies-street station of the Westminster Electric Supply Company. The party will meet at the station at 3·15 p.m.

Polyphase Litigation.—We hear on good authority that the Helios Company, of Cologne, who are the owners in Germany of the Tesla patents, have brought actions at law for infringement against all the firms in Germany who are using the three-phase system of motors. In the United States, as we have already stated, the Westinghouse Company has brought suits against the General Electric Company in connection with the "monocyclic" system. And they have gone so far as to prosecute also the Stanley-Kelly Company for using the Stanley two-phase system, although in the motors of that Company the two circuits are kept separate, and not combined to make a rotatory field. Our British manufacturers will doubtless look on with feelings of gratification at the circumstance that, whoever gains or loses, the battle is being fought at the expense of their rivals.

The Amazon Cable.—Mr. Alexander Siemens, accompanied by Mr. R. E. Peake, of the firm of Clark, Forde and Taylor, consulting engineers to the Amazon Telegraph Company, arrived on the 28th ult. at Para, where they were met by Mr. R. J. Reidy, the Company's general manager out in Brazil. These gentlemen are now on their way up the River to Manaos, the western terminal station of the proposed cable, the intention being, on the return journey, to survey the route of the cable, and also to select landing places and make the necessary landing arrangements at its numerous stations (which number 16 in all), so that on the arrival of the expedition in Brazil shortly, the submersion of the cable may be commenced without delay. The cable will be laid starting from Para. The prospects as to trade and traffic would seem to be exceedingly satisfactory.

A Good Record for an Electric Car.—Car No. 210 of the Marseilles-St. Louis Electric Tramway, after having been overhauled, was put in regular service on the line on January 24th. Up to September 15th it was on the line day for day, covering a total mileage of 22,734 without any accident to the electric parts, the attendance having been reduced to the ordinary cleaning and change of motor brushes. It was taken to the car shop for four days only, in order to repair damage to the truck from collisions and for change of a brake chain. The mean mileage of the 229 days of work was 96, the maximum mileage 129·5. This record shows a very fair result, considering the heavy work of the cars on the line, which has an enormous traffic and steep gradients, and it speaks for the perfection of the electrical equipments now in use on tramways and the security of electric traction under most difficult conditions. The car is equipped with two 18 H.P. Oerlikon motors. Another car, No 205, had previously attained, on the same line, a mileage of 17,000 without any accident either to the truck or to the electric parts.

New French Cables.—According to the Paris *Figaro*, "M. Lebon, Minister of Posts and Telegraphs, has signed a contract for the laying of a submarine cable from Brest to New York, which will be connected with the French telegraphic system in the Antilles. The contract, which bears a large number of signatures, will be presented to the Chambers on the day when they reassemble." The New York shore-end of the New York-Haiti (Antilles) cable, a cable which will have a total length of some 1,500 miles, was laid on September 24th. The two cables together will cost a sum of money calculated to satisfy the most patriotic Frenchman, whilst the fact that these long and expensive lines will be heavily subsidised by the French Government emphasises once more their determination to carry out, at all hazards and at any cost, their policy of colonial expansion with independent cable communications. But how have the requisite landing rights at New York been obtained, seeing that the French Cable Company concerned holds exclusive landing rights in Venezuela, Haiti, and elsewhere?—a fact which has generally been supposed to be a bar to any such cable being landed on the shores of the United States of America.

Argon.—An examination of the gases liberated, says *Nature*, from certain of the sulphurous waters of the Pyrenees reveals, in the hands of M. Ch. Bouchard, the interesting fact that the formerly assumed nitrogen (from which the Spanish physicians have named these waters *azoades*) consists in part of free argon and helium. The collected gas was in each case, after treatment with potash and phosphoric anhydride, introduced into a Plücker tube containing magnesium wire. Under the action of the silent discharge the nitrogen rapidly disappeared by combination with magnesium, leaving a residue exhibiting the characteristic rays of both argon and helium for the gas derived from the waters of la Raillère, helium from the springs of Bois, and helium together with probably an unknown gas from the waters of lowest temperature at Bois. The use of magnesium wire and the silent discharge is due to MM. L. Troost and L. Ouvrard, who show that the magnesium vapour produced very rapidly combines with nitrogen under the conditions obtaining in the tubes. Further, the continued action of a powerful silent discharge, for some hours after the spectroscopic evidence proves the absence of nitrogen, results in a gradual diminution in intensity of the helium and argon rays. Finally a complete vacuum is produced, hence it appears that magnesium combines with argon and helium under these circumstances. Platinum appears to behave like magnesium towards argon in Plücker tubes with the silent discharge.

Military Telegraphy in the United States.—The United States army signal officers have, according to the *Electrical Engineer* of New York, equipped the service with an ingenious arrangement for distributing telegraph and telephone wires. It was found that in laying insulated or naked wire on the ground preparatory to establishing communicating stations, the weight of the reel containing the wire was considerable, and it had to be carried in a handcart. This arrangement required two men in the operation—one to push the cart, the other to wind and unwind the wire. The latest method is to carry the wire on a wheel which is fixed to a bicycle. The rider, by his propulsion of the wheel, distributes the wire in the track of the machine. An ingenious mechanism also permits him to rapidly gather up the wire from the ground, and it is reeled on a spool borne in front of the handle-bar. In front of the saddle this Signal Corps bicycle will support a case of instruments and

Digitized by Google

tools, in addition to the usual leather pocket, in which the bicycle implements are carried. Supported over the rear wheel of the machine, and directly behind the saddle, is the case which contains the telegraphic and telephonic instruments. This can be removed, and a communicating station established anywhere along the line. This bicycle has been tried with much success in Texas, and it will be adopted generally by the signal linesmen. The lightness of the bicycle readily permits its being lifted over obstructions, such as stone walls, hedges, and fallen trees.

The Cause of the Invisibility of the Infra-red Rays.—Infra-red light is invisible to us either because the humours composing the eye are opaque to it, or because the light is incapable of exciting the retina. Cima and Janssen have adopted the former explanation, but the alternative one has been accepted by Tyndall, Engelmann and others, while Helmholtz maintained that the strong absorption suffered by infra-red rays in their passage through the eye is sufficient to account for their invisibility. That they are strongly absorbed has been found by all observers, but Herr E. Aschkinass, says *Nature*, proves, in *Wiedemann's Annalen*, that there is no sudden increase of absorption beyond the red end of the spectrum, and that the absorptive powers of the various media of the eye are practically the same as that of water. The apparatus used for this investigation contained a fluor-spar prism and a bolometer. Thin layers of the humours of an ox eye and a human eye were interposed in the path of the rays from a zircon burner, and the absorptive effects noted by means of the bolometer. It was found that at a wave-length of 0·81 μ, the limit of the visible spectrum, the absorption was 5 per cent. for the whole human eye. This increased to 10·5 per cent. at 0·872, reached 60 per cent. at 0·98, decreased to 34·5 per cent. at 1·095, and finally reached 100 per cent., or total absorption, at 1·4 μ. This shows that a large proportion of infra-red light does reach the retina through the eye, but is not capable of affecting the nerves and producing visual sensation.

The Electrolysis of Alkaline Chlorides.—At the fourteenth annual meeting of the Society of Chemical Industry, at Leeds, the president, Prof. T. E. Thorpe, in his address said with regard to the above:—

"The application of electrical energy to the decomposition of alkaline chlorides either for the production of chlorine, or of alkali, or of both products, has been made the subject of many patents. The great majority of these processes have been stillborn, and even of those which were stimulated into vitality, the existence has been but short and feeble. With a sounder knowledge of the conditions under which success is alone possible, the problem is once more attracting the attention of technologists, and the chemical world is watching with great interest the results of two or three electrolytic processes which are now being worked out on the large scale. One of these is the invention of our member, Mr. Hamilton Castner, which has been in practically continuous operation for nearly 12 months at the Aluminium Company's works at Oldbury. In Mr. Castner's process the difficulties connected with the use of diaphragms and the liability to recombination of the products to form hypochlorite are obviated, whereby the destruction of the electrodes is prevented and a much higher electrical efficiency is obtained. I am indebted to Mr. Castner for the following account of the method:—The essential feature of the process is the employment of a moving body of mercury, which completely separates the products of electrolysis, and by its movement takes the place of a diaphragm, the sodium amalgam formed being decomposed as it is formed. The cell, which is divided into three compartments, is capable of being continuously rocked or tilted, so as to cause the mercury to flow from side to side. The two outside compartments contain the alkaline chloride solution and the carbon anodes, while the middle compartment contains an iron cathode and the caustic solution. The solution of the chloride is continuously circulating through the outside compartments, wherein it is being electrolysed, and then returns to saturators, where it is re-charged with salt. The electric current traversing the salt solution liberates chlorine and forms sodium amalgam. The chlorine escapes from each cell through an aperture into a collecting main, while the sodium amalgam, by the continuous back-and-forward tilting of the cell, passes to the centre compartment, where it acts as an anode during the passage of the current, the sodium going into solution as caustic. A regulated quantity of water is admitted hourly to the centre compartment of each cell, causing the pure solution of caustic to overflow through a discharge pipe into a large collecting pipe connecting all the cells. The cells are electrically connected in series, and are capable of being cut out or put into operation at will."

Exhibition of Horseless Carriages.—Sir David Salomons has arranged for an exhibition of horseless carriages on Tuesday, October 15th, at the Tunbridge Wells Agricultural Show Ground, which has been kindly lent him for the occasion. The carriages will enter the ring at three o'clock p.m. The grand stand is reserved for those attending by invitation. In order to offer all interested in these new carriages an opportunity to attend, the ground will be thrown open to the public on payment of one shilling entrance fee. Sir David Salomons is paying the expenses of the exhibition, and intends to apply the entrance money to the purchase of prizes to be awarded at the show of the Tunbridge Wells and South-Eastern Counties Agricultural Society next year, for the best horseless carriages intended to be used for agricultural, trade and private purposes. For the convenience of those desiring to be present, Sir David Salomons has written an article giving infromation on the subject, which will be published in the leading Tunbridge Wells journal, the *Kent and Sussex Courier*, on October 4th. This article also replies to the very large correspondence which has been received and to which it has been found impossible to reply in detail. Invitation tickets for the exhibition may be secured in order of application by fellows and members of any of the following institutions sending an addressed envelope to the secretary of the Institution of Civil Engineers, 24, Great George-street; the Institution of Electrical Engineers, 28, Victoria-street; the Institution of Mechanical Engineers, 10, Victoria-chambers; the Royal College of Surgeons, Lincoln's Inn Fields; and the Royal College of Physicians, Pall Mall East. It must be understood that if applicants do not receive a reply within three days it has not been possible to send an invitation.

Current Electrical Science.—*Wiedemann's Annalen*, No. 8, contains the usual amount of learned dissertation relieved by some striking experimental work. Victor Biernacki describes a simplified form of Hertz's Reflection Experiment. He places one of Dr. Lodge's "coherers" in the focal line of the secondary mirror, and uses mirrors as small as 45 x 30cm., with a focal length of 3cm. These need only be 4in. apart. The polarisation of electric rays may be shown by reflecting them at the surface of a tiled stove. At an angle of 60deg. all reflection ceases. A piece of good ice introduced between the mirrors perceptibly rotates the plane of polarisation. A Bohemian physicist, Franz Kolácek, gives a new method of determining Small Self-Inductions by the mechanical action of variable magnetic fields upon closed circuits. A closed coil is suspended in a homogeneous periodic magnetic field, and the force necessary to prevent torsion is measured. Tesla's Experiments are treated theoretically by A. Oberbeck, who shows that the Tesla discharge invariably consists of two oscillatory discharges of different frequencies. These frequencies are not the same as those of the primary and secondary circuits by themselves. In one case, where the latter were both 10 millions per second, the frequencies of the two discharge currents were 8 and 15 millions respectively. A simple and elegant method for determining the Electric Indices of Refraction of Liquids is described by P. Drude. He uses a small Blondlot exciter, with wires no longer than the breadth of this page. The further portion of the wires is conducted through the liquid, and the wave length in the liquid found by shifting certain bridges along the wires outside and inside the liquid. G. Jaumann deals another blow at the alleged Constancy of Spark Potential, and specifies variations of force, light, degeneration and recovery of the spark gap, &c., as causes affecting the discharge. J. Elster and H. Geitel make another of their highly suggestive contributions to the subject of Photo-Electric Currents, and come to the conclusion that the effect of polarised light upon the discharge from the liquid K—Na cathode is due to the direct influence of the electric oscillations produced at the surface of the metal.——In the *American Journal of Science* for September we find a clever Paper by L. A. Bauer on the distribution of Terrestrial Magnetism. He starts from the supposition of a globe magnetised symmetrically with respect to its axis of rotation, and shows that the chief cause of distortion of this primary symmetrical field can be represented as due to a secondary polarisation approximately equatorial in direction. The equatorial system, to account for the existing anomalies of distribution, would have to be about five or six times weaker than the polar system. To the conundrum—Is the earth a magnet or an electro-magnet?—the author does not return a definite solution

ELECTROMAGNETIC THEORY.—LXXV.*

BY OLIVER HEAVISIDE.

(*Continued from page 668.*)

§ **292.** When the impressed force is intermediate, say at the point $x = y$, the treatment is quite similar, so that very little detail need be given. We have the operational solutions (35), (36), § 259, in which put y for a. Now circularise the functions by putting $q = si$. Remember in doing so that this is not really a complex transformation, because the operators are rational functions of p already, and therefore of s^2. This fact makes the transformation easy, by the cancelling of terms that occurs. The result is that

$$V_1 = \frac{(R\cos - Z_0 s\sin)sy\,.\,(Z_1 s\cos + R\sin)s(l-x)}{\cos sl(R^2 - Z_0Z_1s^2)\left(\tan sl + \dfrac{Rs(Z_0+Z_1)}{R^2 - Z_0Z_1s^2}\right)} e \qquad (71)$$

expresses the potential due to e at a point x on the right side of y, where e is situated. To obtain the corresponding expression for V_2, where x is on the left side of y, refer again to (35), (36), § 259, and observe that V_2 is got from V_1 by interchanging α and β, x and $l-x$, y and $l-y$, and then negativing the result. So, doing the same to (71), we get

$$V_2 = -\frac{(R\cos - Z_1 s\sin)s(l-y)\,.\,(Z_0 s\cos + R\sin)sx}{\text{same denominator}} e. \qquad (72)$$

Now apply the expansion theorem. The outside terms for the steady state may be perhaps most easily got by elementary considerations—by Ohm's law and the condenser law, that is to say. When the steady terminal resistances (effective) are finite, say R_0 and R_1, we shall have

$$V_1 = \frac{R(l-x)+R_1}{Rl+R_0+R_1}, \quad V_2 = -\frac{R_0+Rx}{Rl+R_0+R_1}, \qquad (73)$$

by Ohm's law. But when R_0 and R_1 are both infinite, and there are terminal condensers concerned, we must go further, and apply the condenser law, say as in § 291, equation (64), which is a special case of the present. In general, however, should the terminal arrangements include several condensers, it is the effective steady permittances of the combinations that are to be regarded as S_0 and S_1 in the place referred to. Or, we may get the steady states directly out of (71) and (72) by seeking their limiting values where $s = 0$. However the work be done, denoting the steady states by v_1 and v_2, and applying the expansion theorem to (71), we obtain at once

$$V_1 = v_1 + \Sigma \frac{(R\cos - Z_0 s\sin)sy\,.\,(Z_1 s\cos + R\sin)s(l-x)}{\frac{1}{2} sl\cos sl(R^2 - Z_0Z_1s^2)\left(\sec^2 sl + \dfrac{d}{d(sl)}\dfrac{Rs(Z_0+Z_1)}{R^2 - Z_0Z_1s^2}\right)}\epsilon^{pt}, \qquad (74)$$

by introducing the summation sign, the time factor, and changing the denominator by the operation $\frac{1}{2}sl(d/d(sl))$.

As regards V_2, we may get its formula by making the interchanges already indicated, in getting (72) from (71). But this is quite unnecessary. For, by inspection of the original operational formulæ (35), (36), § 259, we may see that when the denominator vanishes V_1 and V_2 become identical in those equations. That is, identical for all the values of p given by the determinantal equation, though not in the case of $p = 0$, which finds the steady states on the two sides of e. So the V_2 formula is to be got from (74) by changing V_1 to V_2 and v_1 to v_2. The expansional part is the same, in virtue of the special values of sl. Of course, we may use the alternative formula if we like, making the interchanges before described. And when the Z's are explicitly given, simplifications of form may be readily carried out. This is not a matter of indifference, if numerical calculation is wanted, because, of two equivalent forms, one may be much more manageable than the other.

§ **293.** The determinantal equation is (66) or (67). Say,

$$\tan sl = \phi(sl) = -\frac{Rl(Z_0+Z_1)sl}{(Rl)^2 - Z_0Z_1(sl)^2}. \qquad (75)$$

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Here $\phi(sl)$ is a rational function of sl. Draw the curves

$$y_1 = \tan sl, \qquad y_2 = \phi(sl); \qquad (76)$$

the abscissæ being sl, and the ordinates y_1 or y_2. The intersection of these curves indicates the admissible values of sl. It is sufficient to draw them very roughly, just to find the general situation and rough values of the roots. Only a few at the beginning are wanted, except for very small values of the time. I mentioned before that when the Z's are mere resistances, tangent tables readily find the roots. Use the graphically-obtained values as a first approximation. Say it is the first root, which is the most important in general. The tables may show that the rough value is several degrees wrong. Estimate the correction by rule of three. Apply the revised value to the tables. It will be nearly right, and a second revision may bring it right to a minute, and a third to a second.

Another easy case is that of terminal condensers. Also the case of condensers and resistances does not trouble much. And it may be remarked here that when the terminal arrangements involve only electric energy, without magnetic, the roots are always real, so that the above described process can be followed. But it is not so easy when magnetic energy is involved. There may then be complex roots as well. This occurs even when a single coil is concerned at either terminal, if the inductance be of a suitable value. Of course, in slow cable working, the inclusion of the effect of the self-induction of the coils is not an important matter, and the coils may be treated as resistances. The trouble with complex roots sets a limit to the desirability of elaborating formulæ beyond the point of ready systematic calculation. The formulæ, nevertheless, have an interest of a scientific kind, as showing what may be done if the necessary trouble be taken.

The determinantal equation may be written

$$\tan sl + \tan\left(\tan^{-1}\frac{sZ_0}{R} + \tan^{-1}\frac{sZ_1}{R}\right) = 0, \qquad (77)$$

which makes

$$n\pi = sl + \tan^{-1}\frac{Z_0 sl}{Rl} + \tan^{-1}\frac{Z_1 sl}{Rl}. \qquad (78)$$

This form shows how the difference between sl and the standard value $n\pi$, n being a positive integer, depends upon the terminal operators. Equation (78) may be readily converted to a power series, perhaps with occasional advantage. Special formulæ may also be constructed exhibiting the roots explicitly to any desired degree of accuracy, but it is questionable whether they repay the labour of obtaining them, when tables of circular functions are so useful. General principles may become smothered by overmuch detail.

The original form of the determinantal equation, as it shows itself in the operational solutions (35), (36), § 259, and (65), (66), § 253, may be written

$$\epsilon^{2ql} = \alpha\beta, \quad \text{or} \quad \alpha\epsilon^{-ql}\beta\epsilon^{-ql} = 1. \qquad (79)$$

If the left-hand operator be applied to a wave originated at a point, say at $x = 0$, the resultant would represent what it became after a journey to $x = l$, reflection there, according to β, followed by a journey to $x = 0$, and reflection there according to α. The right-hand member would show that the effect of the cycle of operations was to restore the disturbance to its original state. This is impossible, of course. But it is apparently done on a normal solution. Thus

$$\alpha\beta\epsilon^{-2ql}\epsilon^{Pt} = \epsilon^{Pt}, \qquad (80)$$

if the constant P is chosen to be any one of the values given by the determinantal equation. This equation does not imply any use of $p^{\frac{1}{2}}$, but only abbreviates a rational equation. Clear it of fractions, and we get

$$\left\{\left(1+\frac{qZ_0}{R}\right)\left(1+\frac{qZ_1}{R}\right)\epsilon^{ql} - \left(1-\frac{qZ_0}{R}\right)\left(1-\frac{qZ_1}{R}\right)\epsilon^{-ql}\right\}\epsilon^{Pt} = 0, \qquad (80\text{A})$$

when the operator is an even function of q, and is therefore rational.

In the above equation (74) we have not only solved the question of the establishment of a certain state by an impressed force, but also the connected question of the

Digitized by Google

subsidence of that state to equilibrium when the force is removed. For, if we write (74) and its companion thus,

$$V = v - \Sigma u\epsilon^{pt}, \qquad (81)$$

where v has to be v_1 or v_2 as the case may be, we have, initially,

$$v = \Sigma u. \qquad (82)$$

That is, the state of potential v is expanded in the special Fourier series concerned. If, then, v is left to itself, unsupported by impressed force, the state at time t later will be given by

$$v_1 = \Sigma u\epsilon^{pt}, \qquad (83)$$

where v_1 is what v then becomes.

There is this remark to be made about (82). It cannot be called without limitation *the* expansion of the function v in a Fourier series, subject to the terminal differential conditions, for it may be only one of many expansions expressing the same functions v, and subject to the same differential conditions. This is quite clear in the physics of the matter. For consider what the impressed force does in the act of setting up the state v. It energises the terminal arrangements as well, electrically and magnetically, except when only mere resistances are concerned. Now the same state of potential v in the cable may be accompanied by various states of energy terminally, and all due to the same impressed force. So when we take off the impressed force we not only let the charge redistribute itself, but also let the terminal energy act on the cable, and in various manners according to circumstances. Equation (83) exhibits the potential at time due to the initial state u in the cable, *and* to the accompanying initial states of the terminal arrangements. This is true even when the Z's are only given by formulæ, and we do not analyse them to see what particular arrangements are really represented thereby, and what the terminal energies are.

It will be seen that the expansion theorem is a labour-saving agent of a remarkable character. For it is not from formulæ representing the expansion of an arbitrary initial state that we can most readily learn the general course of events in the physical problems concerned. We should rather prefer to examine the result of some special initial state, or the result of a disturbance initiated at a single spot, as an impulsive or a continued source. Now it is just in these cases that the expansion theorem shows to best advantage. We obtain our formulæ in a very ready manner, without the circumbendibus connected with arbitrary initial states and the conjugate property of the normal functions. We shall see presently how to apply the expansion theorem to arbitrary initial states. In connection therewith, it may be noted here that an integration applied to (74) and its companion enables us to express the effect due to an arbitrary distribution of impressed force along the line, all starting at the same moment in the simplest case. Put $e\,dy$ for e, and let e be a function of y. Then integrate with respect to y from 0 to l, using one or other formula, according as x is to right or left of the elementary impressed force concerned. But this is a mathematical development which is useless for our present purpose.

§ **294.** The expansion of an arbitrary function of x between the limits 0 and l naturally rests upon the expression of the function for a single point. That is, we require to find how a charge Q, initially all at the point y, diffuses itself when controlled by given terminal conditions. As was before pointed out, the construction of the operational solution for a point charge is like that for an impulsive impressed voltage, with a difference. The latter produces a jump in the potential, the former in the current, at the place of application. A continued impressed force e at a point has its analogue in a continued source of current, led in by an auxiliary wire. The operational solutions to right and left of the source are given by (65), (66), § 263, in which h is the current introduced, to be given as a function of the time. Taking $h = pQ$ makes the source impulsive, and the case is then that of an initial charge Q. So, by (65), § 263, the potential V_1 at x, on the right side of the point y, where Q is impulsively introduced, is given by

$$V_1 = \frac{\epsilon^{qy} + \alpha\epsilon^{-qy}}{\epsilon^{ql} - \alpha\beta\epsilon^{-ql}}\left\{\epsilon^{q(l-x)} + \beta\epsilon^{-q(l-x)}\right\}\frac{qQ}{2S}. \qquad (84)$$

On the left side of y the potential V_2 is to be got by simply interchanging x and y in the last formula.

Converting (84) to circular functions, by means of $q = si$, makes the equivalent formula

$$V_1 = -\frac{(Z_0 s\cos + R\sin)sy\,.\,(Z_1 s\cos + R\sin)s(l-x)}{\cos sl(R^2 - Z_0Z_1s^2)\left(\tan sl + \dfrac{Rs(Z_0+Z_1)}{R^2 - Z_0Z_1s^2}\right)}\frac{sQ}{S}. \qquad (85)$$

The final state must be either zero or constant. It must be zero if there is conductive connection with earth at either terminal—that is, when at least one of R_0 and R_1 is not infinite; and it must be finite when both are infinite, so that the charge Q cannot be got rid of. In the former case, the last equation shows the result at once, on account of the s which occurs as a factor. In the latter case, it is the permittance that controls matters. The charge Q is finally either uniformly distributed along the cable, if there is no terminal permittance, or is divided between the cable and the terminal condensers. Thus, the potential of the cable is

$$v = \frac{Q}{Sl + S_0 + S_1}, \qquad (86)$$

if S_0 and S_1 are the effective permittances of the terminal combinations. This result may be dug out of (85), but is sufficiently clear without doing that, which is, however, a useful test.

Applying the expansion theorem to (85), we obtain

$$V = v - \Sigma\frac{(Z_0 s\cos + R\sin)sy\,.\,(Z_1 s\cos + R\sin)s(l-x)}{\cos sl(R^2 - Z_0Z_1s^2)(\sec^2 sl - \phi'(sl))}\frac{2Q}{Sl}\epsilon^{pt}, \qquad (87)$$

where $\phi(sl)$ is as in (75) and $\phi'(sl)$ in its derivative. We have the same form of determinantal equation. This formula applies on both sides of the point y, both as regards the steady v and the summation. For the steady state is constant, and the original operational solutions (65), (66), § 263, become the same when the denominator vanishes. We may, however, exchange x and y in (87), and make other changes controlled by the determinantal equation.

Put $Q/S = 1$ and $t = 0$. Let u be the result. Then

$$u = u_0 + \frac{2}{l}\Sigma\frac{(Z_0 s\cos + R\sin)s(l-y)\,.\,(Z_1 s\cos + R\sin)sx}{\cos sl(Z_0Z_1s^2 - R^2)(\sec^2 sl - \phi'(sl))} \qquad (88)$$

where u_0 is the value of v with $Q/S = 1$. Here u represents the initial state. Therefore u is the expansion of the unit impulsive function of x concentrated at the point y. It represents a great deal more than that, outside the limits 0 and l, for there are periodic repetitions, though not periodic in the usual sense, except in the elementary cases of total reflection at the terminals, when we have the usual Fourier series with regularly spaced roots.

Given, then, a function $f(x)$ representing an initial state, its expansion is

$$f(x) = \int_0^l f(y)u\,dy, \qquad (89)$$

using the previous expression for u; and, by introducing the time factor in the summation, we find what the potential $f(x)$ becomes at time t. The ultimate result is a state of uniform potential—viz., the total initial charge divided by the total permittance, including the effective terminal permittances.

As regards the meaning of the expansion for V outside the limits for x, viz., 0 and l, which are imposed in the physical problem, we get some knowledge from the determinantal equation. If V is the potential at x at time t in the cable, free from impressed force, its general characteristic is $(\Delta^2 - q^2)V = 0$, where Δ is the space differentiator and q^2 is RS × the time differentiator. Also, when the terminal reflection coefficients α and β are introduced, we make V satisfy

$$\left\{\left(1+\frac{\Delta Z_0}{R}\right)\left(1+\frac{\Delta Z_1}{R}\right)\epsilon^{l\Delta} - \left(1-\frac{\Delta Z_0}{R}\right)\left(1+\frac{\Delta Z_1}{R}\right)\epsilon^{-l\Delta}\right\}V = 0, \qquad (90)$$

where in the operator on V we write Δ for q. Compare with (80A). It is to be understood that in the two Z's the same change is made, or Δ^2/RS substituted for p. So, if V is $f(x)$, we have, by Taylor's theorem, § 276,

$$\left(1+\frac{Z_0\Delta}{R}\right)\left(1+\frac{Z_1\Delta}{R}\right)f(x+l) = \left(1-\frac{Z_0\Delta}{R}\right)\left(1-\frac{Z_1\Delta}{R}\right)f(x-l). \qquad (91)$$

Digitized by Google

This is the equation showing the functional connection between the values at points distant $2l$ from one another. When the Z's are zero, it reduces to $f(x+l)=f(x-l)$, showing the primary kind of periodicity. Further examination of (91) to see how this is modified by the terminal operators, would lead us too far away from the proper subject.

§ **295.** The expansion (89), subject to (88), has some right to be termed *the* expansion of $f(x)$ in the Fourier series in question, because it is the one that depends only upon the initial state of the cable. It gives the potential at any later time on the understanding that the terminal arrangements are initially unenergised. Unless, therefore, the Z's are mere resistances, the Fourier series (89), (88), may not be the proper one to use in the physical problem. It will still represent the initial state, but will fail later, should the terminal arrangements be initially energised. So there are, independently of the above expansion, others which represent zero initially, and which only come into operation when t is finite. The number of such auxiliaries is determined by the number of independent ways in which the terminal arrangements may be energised. It may, therefore, be finite or infinite. If, for example, there is a coil at A and a condenser at B, there are just two auxiliary expansions. For the full specification of the initial state must include not merely the state of charge in the cable, but also the charge of the condenser and the current in the coil. After the first moment, they are all connected. Initially, they are independent.

A case in which there is an infinite number of auxiliaries is got by letting the terminal arrangement at either end be a second cable, of finite length. Another one is got by putting a piece of metal inside a coil. Without the metal the coil would introduce one auxiliary. The metal, however, which will produce a quite determinate rational terminal operator, will introduce an infinite number of auxiliaries, because the initial state will require a specification of the magnetic force in all parts of the metal, and this initial state may be arbitrary. This case may seem fearfully complicated, but can be worked out (in the case of a round core), without great difficulty, by the operational method.

To show the action of a single auxiliary, let there be a terminal condenser. Say that $Z_0=(S_0p)^{-1}$ and $Z_1=0$. Then the cable is earthed direct at B, and through a condenser of permittance S_0 at A. So, by (85) above,

$$V_1=\frac{\left(\frac{S}{sS_0}\cos-\sin\right)sy\,.\,\sin s(l-x)}{\cos sl\left(\tan sl-\frac{S}{S_0 s}\right)}\frac{sQ}{S} \qquad (92)$$

represents the potential at x on the right side of y, due to the impulsive introduction of Q at y. And this expands to

$$V=\Sigma\frac{\left(\frac{S}{S_0}\cos-s\sin\right)sy\,.\,\sin s(l-x)}{\frac{1}{2}sl\cos sl\left(\sec^2 sl+\frac{Sl}{S_0 s^2 l^2}\right)}\frac{Q}{S}\epsilon^{pt}, \qquad (93)$$

which is valid on both sides of y. There is no outside term The determinantal equation is

$$\tan sl=S/S_0 s, \qquad (94)$$

and an integration according to (89) constructs the potential due to an arbitrarily given state in the cable, with no initial charge in the condenser.

Now as regards the condenser, put $y=0$ in (92). Then

$$V_1=\frac{\sin s(l-x)}{\cos sl(\tan sl-S/S_0 s)}\frac{Q}{S_0} \qquad (95)$$

represents V_1 in the cable due to Q at its beginning. That is, to an initial charge Q of the condenser. Or, if V_0 is its initial potential we may substitute it for Q/S_0. So

$$V=V_0\Sigma\frac{\sin s(l-x)\epsilon^{pt}}{\frac{1}{2}sl\cos sl\,(\sec^2 sl+Sl/S_0 s^2 l^2)} \qquad (96)$$

represents the potential V at time t in the cable due to V_0 alone. Initially we have

$$0=V_0\Sigma\frac{\sin s(l-x)}{\text{same denominator}}, \qquad (97)$$

for any finite x in the cable. This exhibits the auxiliary expansion, V_0 being any constant. The complete expansion, showing V due to the initial V_0 on the condenser and $V=f(x)$ in the cable, is therefore

$$V=\Sigma\sin s(l-x)\epsilon^{pt}\frac{V_0+\int_0^l f(y)\left(\frac{S}{S_0}\cos-s\sin\right)sy\,dy}{\frac{1}{2}sl\cos sl(\sec^2 sl+Sl/S_0 s^2 l^2)}. \qquad (98)$$

This case is peculiar, inasmuch as the same operational solution serves for the elementary charge in the cable and for the terminal charge. The distinction is that Q is finite in one case and infinitesimal in the other. It is true that in (92) Q may be finite, but when we pass to an initial finite distribution of potential, it is replaced by Q dy, the charge on the element dy, which is therefore infinitesimal. On the other hand, the Q for the condenser is finite.

§ **296**. Another consideration presents itself here. It is a common error that only finite functions can be expanded in Fourier series. That this is wrong may be seen by the above investigation. Go back to (88). Let there be initially Q_1/S at y_1, Q_2/S at y_2, and so on up to Q_n/S at y_n, these points being separate. Then

$$v=\Sigma\frac{Q_n}{S}u_n\epsilon^{pt} \qquad (99)$$

will, by (88), represent the potential at time t due to the n point charges. Initially, v is zero except at the n points, but there it is infinite, with finite space totals, however. Combine with (98). If $f(x)$ is finite and continuous, $V+v$ is initially finite and continuous, except at the n points, where finite charges exist.

Nor need these condensations be themselves finite. The Q's may be infinite. It is, indeed, true that an infinite charge suddenly introduced at a point y would in an infinitely short time raise the potential of the whole cable infinitely. In this respect the solution would be of a useless nature. But we may combine the infinities so as to have finite results. The simplest case is first to have two finite point charges Q and − Q at distance z apart. Then bring them closer, increasing Q in the same ratio, so that Qz is finite. In the limit we have a point source involving a double infinity in Q, and a corresponding expansion of the potential in a F. series. Similarly as regards poles of higher multiplicity.

Nor does the matter end here. If the self-induction of the line be included, the initial state must include a specification of the initial current, as well as of V. Fourier series are involved, and such a series has to express the initial potential, whilst a connected series expresses the initial current. There may be points of initial infinite condensation in both series.

Another common error is that the expansion of a function in a series of sines and cosines of $n\pi x/l$, n being integral, is uniquely determined by Fourier's theorem. There are other expansions. To show this (in one way), let $Z_1=-Z_0$ in (85). Then $\tan sl=0$, or $sl=n\pi$, as in Fourier's theorem. But now $R^2-Z_0Z_1s^2=0$ also, or $R^2=Z_0^2q^2$, determines a distinct set of extra normal systems, of the type ϵ^{hx}, where h is constant. So we can expand a given function in terms of the usual $\sin sx$ and $\cos sx$, and the extra functions. The result is, therefore, to represent another function of x expanded in terms of the usual sines and cosines, with equally-spaced roots. But it is not the expansion got by Fourier's theorem, though it is equally true. I will give one or two examples in illustration of this.

(To be continued.)

MOLECULAR ELECTRICITY.

BY J. H. POYNTING, SC.D., F.R.S.

(Concluded from page 712.)

Now let us take a conducting dielectric such as water. As guiding us to an account of what goes on we have the facts (1) that, however small the E.M.F., conduction and presumably electrolysis take place, and no finite difference of potential can be maintained between the electrodes unless we continually supply fresh energy, and (2) that a solute such as sulphuric acid, which appears to combine with the solvent in some way,

Digitized by Google

enormously increases the conductivity. From (1) we gather that some of the molecules must be just ready for change of partners, and from (2) we may at least guess that molecular groups are formed much more complex than the atomic pairs we have hitherto dealt with. We can see how such molecular groups might arise by the straying out and coalescence of induction tubes of neighbouring molecules, and the consequent formation of new connections. Thus, if two pairs come together, as in Fig. 17 (*a*), we may have them connected into a single group, such as (*b*), and any number of molecules may be brought into circuit in the same way, so that we may have a parallel

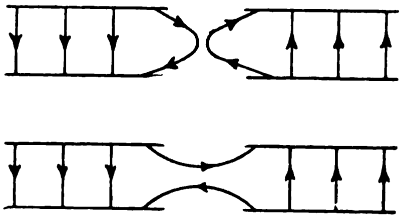

FIG. 17.

arrangement as in Fig. 18. Or if the coalescence occurs by the approach of two or more groups, such as Fig. 17 (*b*), we may have a series arrangement as in Fig. 19, the kind which we shall suppose to be effective in conduction. We must further suppose that small quantities of acids or salts in solution enormously increase the number of complex molecules. Some of these groups would appear to be more energetic than the initial pairs. Probably on that account they are continually breaking up and re-forming, the energy of translation being no doubt converted at each collision and reformation into energy of electrical separation. There are no doubt all

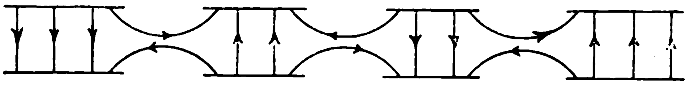

FIG. 18.

degrees of connection from those of Fig. 17 (*b*) and Fig. 19, where the result may be obtained practically by adding one closed ring tube of induction to a series of pair-molecules to the case where the tubes from each atom go half one way and half the other. But I imagine that at any given instant only a small fraction of the molecules are thus connected into groups or circuits.

If a tube of induction running from above downwards moves sideways into such a group as that in Fig. 19 or Fig. 20 (*a*), it finds the right side made ready for it, and we may possibly

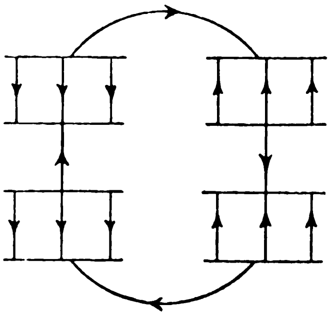

FIG. 19.

have in succession Fig. 20 (*a*) (*b*) and (*c*), where we suppose that the left-hand side splits up into pairs, while the right-hand remains threaded on the incoming line. When a liquid contains many such groups, some of the chains of molecules are almost ready made, and the chains are very easily completed from plate to plate, since the entering tubes have only to furnish a link, as it were, here and there. The "electric elasticity" $1/K$ will be a sort of average of the elasticities or of the difficulties of forming chains in all the various kinds of molecules present. To give a numerical illustration, let us have two condenser plates in a liquid in which we suppose that in the simply paired molecules, such as those on the left in Fig. 20 (*c*), the value of K is 1·77. Let us suppose also that these occupy 99 per cent. of the paths from plate to plate, while the other 1 per cent. is occupied by very much connected molecules with K equal to 7,500. Then if the capacity of the condenser in air were C, it would be with this arrangement of molecular paths

$$\frac{99 \times 1{\cdot}77\,C + 7{,}500\,C}{100} = 76{\cdot}76\,C,$$

or the resultant specific inductive capacity is 76·76.

But this is only true in the mass. If we have very minute electromagnetic waves going through the liquid they will for 99 per cent. of the molecules use $K = 1{\cdot}77$. For a very large fraction of the remaining 1 per cent. they will probably also use this K, for they are not concerned with the group as a whole, but only with the individual members to which they add or from which they subtract small quantities of induction; and as long as the points representing these members of groups are on the straight part of the characteristic their K for waves is still 1·77. We may therefore expect the value for small waves generally to be very little more than 1·77.

This appears to indicate a possible explanation of the high inductive capacity of such substances as water and alcohol. Accompanying this high value there is generally conductivity

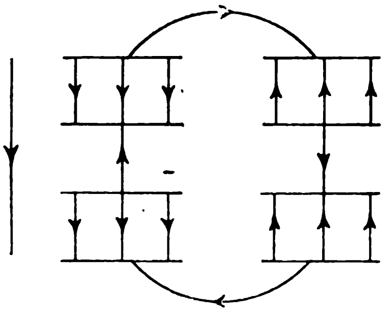

FIG 2 *a*.

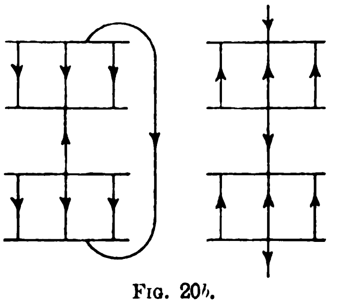

FIG. 20*b*.

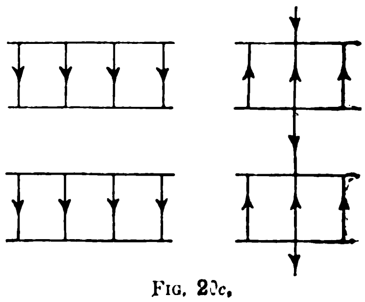

FIG. 20*c*.

and no doubt electrolysis. If we suppose that some of the groups are already so far towards decomposition that half the tubes from each atom run one way and half the other, tubes entering the substance will concentrate on such groups, for a further addition of induction will yield energy instead of requiring it, and the point of instability being passed electrolysis will occur. Perhaps even before the tubes are thus evenly divided, tubes entering the substance may prefer to pass through the groups rather than through the simply paired molecules, for while more energy may be stored in the one half of such a group as that represented in Fig. 20, when a new tube enters in it, less may be required in the discarded half, and so on the whole energy may be given up. But it does not seem possible to give any satisfactory account of the process in our ignorance of the real constitution of the complex molecules. All we can say is that some such process probably occurs, inasmuch as conduction does occur even with the smallest external E.M.F.

We may perhaps suppose that in metallic conduction we have a similar process. If the metallic molecular structure is very complicated, with many groups having unstable, or nearly unstable, construction then tubes of induction entering a metal

Digitized by Google

will select such groups in preference to the more simple stable molecules and electrolyse them. To account for the absence of transfer of atoms along the line of current we must, I think, introduce the supposition of change of charge as already explained on p. 671, and to account for the continuance of conduction we must suppose that there is a continuous formation of new groups as the old ones are broken up. Perhaps we have here some key to the rise of resistance with rise of temperature. As the molecules become more energetic we may expect that the groups will be more broken up by the motions of vibration and translation, and that the number of unstable groups is diminished and their rate of formation is decreased. Hence the entering tubes will find fewer groups ready for them, and if the external E.M.F. remains constant, the rate at which the tubes are dissipated will be decreased. The difficulty of such explanation consists in understanding its inapplicability to electrolytes. Perhaps, too, we have here a hint as to the superior conductivity for heat of metals. If a metal consists largely of many-atomed groups entangled together, and continually breaking up and re-forming, energy supplied to one molecule will, we may imagine, be more readily transferred to its neighbours than if each molecule is self-contained and permanent. This will certainly be the case if energy given to an atom in a molecule is more rapidly transferred to its fellows in the same molecule than to atoms at the same distance in the surrounding molecules. To use an illustration which may put the suggestion in a clearer way, news will be transmitted through a population dwelling in villages and towns much more rapidly than through an agricultural population of the same average density scattered over a country in isolated homesteads.

The theory which I have been trying to set forth may be regarded as a theory of the conservation of induction tubes, and of their beginning and ending on atoms. That the atoms always have charges on them, and therefore have tubes proceeding to or from them, appears to be generally held as necessary if we accept the electromagnetic theory of light. If the molecules give rise to waves of electric induction they must necessarily be electric systems, and their parts must almost certainly be bound together by electric forces. Whether it is possible for an induction tube to exist without atoms is merely a matter at present of speculation. At present we know of no such thing. If such a tube do exist, it can only be as a closed ring, like a closed ring tube of magnetic induction round a current, for an unclosed tube would have opposite charges at its ends in free space, and charges not on matter are so entirely outside experience that we cannot accept their existence. The weight of evidence appears to me rather against the view of matter-free induction, and though at first we might be inclined to think that the passage of light waves across interstellar space implied such induction, yet even in this case we have possibly quite enough matter to supply atomic ends for the tubes to attach themselves to. If we accept the electric discharge theory of comets' tails we apparently assume the existence of enough matter to carry electric induction from a cometic nucleus outwards. I suppose that the theory implies that the nucleus is charged in one way, say positively, and that it has become separated from the matter bearing the negative, which remains far out in space. The sun is itself to be regarded as charged with the same sign as the nucleus, while the corresponding solar negative is also somewhere in space. When the induction of the comet is added to that of the sun the strain is sufficient to break down the feeble insulation of interplanetary space, and a discharge results straight out, or nearly straight out from the nucleus, and this discharge is through the interplanetary matter. But though this appears to be the only reasonable account of the discharge theory, after all it is bringing little more than a speculation to bolster up another speculation, viz., the existence of matter sufficient to carry waves of induction in the interatomic form wherever light waves travel.

At first sight this theory of molecular electricity appears to be very different from the chemical dissociation theory now generally held; but if the dissociated atoms of that theory have charges, they have also tubes of induction proceeding from the charges. When the tubes are taken into account they must, I believe, lead to some such hypothesis as that of which I have attempted an inadequate and imperfect explanation. I am only too deeply conscious of the difficulties unsurmounted. But in working at the subject I have felt all through that, since so much is nearly but not quite explained, there must be hope of progress on these or similar lines if we can only supply some as yet unrecognised idea. Perhaps the very imperfections of my account may stimulate some reader to take up the subject afresh from some better point of view, and, with new ideas, achieve success.

THE ELECTRIC ARC.

BY HERTHA AYRTON.

(Continued from page 639.)

In their Paper published in the American *Electrical Engineer* for August 2, 1893, of which I have already given an abstract (pp. 638, 639, *The Electrician*, September 13th), Messrs. Duncan, Rowland and Todd, after quoting—not quite correctly—the equations employed by various experimenters to connect the P.D. between the carbons with the current flowing and the length of the arc, said: "In fact, almost any results may be obtained by modifying the size and composition of the carbons." I shall show, however, from the results of the very experimenters whose equations they quoted that this is not the case, and that the *form* of the true equation connecting these variables is the same whatever the size of the carbons may be, and whatever their composition, as long as the carbons are solid. The values of the constants in the equation will, however, doubtless depend on the hardness of the carbons, and perhaps on their size.

It will be found, also, that although in certain cases my equation does not support the conclusions arrived at by previous experimenters, it is really more in accordance with the results of their own experiments than were the conclusions they themselves deduced from them.

If we take equation (4) in the form

$$W = 38{\cdot}88\,A + 11{\cdot}66 + (2{\cdot}074\,A + 10{\cdot}54)\,l. \quad (5)$$

and put $A = -\dfrac{10{\cdot}54}{2{\cdot}074}$ in it,

we have $W = 38{\cdot}88 \times \left(-\dfrac{10{\cdot}54}{2{\cdot}074}\right) + 11{\cdot}66,$

that is, we have two values for A and W which are independent of the value of l, showing that all the lines connecting A and W for the various constant lengths of arc must pass through one point, the co-ordinates of which are

$$A = -\frac{10{\cdot}54}{2{\cdot}074}$$

and $W = -38{\cdot}88 \times \left(-\dfrac{10{\cdot}54}{2{\cdot}074}\right) + 11{\cdot}66;$

or, $A = -5{\cdot}08$

and $W = -185{\cdot}92.$

Similarly, by putting $l = -\dfrac{38{\cdot}88}{2{\cdot}074}$, the coefficient of A disappears in the same equation, and we find that all the lines connecting W and l for the various constant currents must pass through a point, the co-ordinates of which are

$$l = -18{\cdot}7,$$
$$W = -185{\cdot}92.$$

Hence the laws upon which equation (4) is founded, and upon which it depends absolutely, may be put in the following form:—

1. The curves representing the connection between power and length of arc for various constant currents are straight lines.

2. The curves representing the connection between power and current for various constant lengths of arc are straight lines.

3. The straight lines representing the connection between power and length of arc for constant currents all meet at a point, both co-ordinates of which are negative.

Digitized by Google

4. The straight lines representing the connection between power and current for constant lengths of arc all meet at a point, both co-ordinates of which are negative.

I shall now proceed to show that these laws are true, not only for the results of my own experiments, but also for the results of all the other experiments made with solid carbons that I have been able to find, of which detailed information has been published regarding the numbers.

Edlund gave only the ratios of the currents he used, so that it would not be possible to construct a complete equation, including all three variables from his results; but the equation he discovered, $r=a+b\,l$ for constant currents, is really another form of the first law I used, for if we multiply this equation throughout by the constant A^2 we obtain an equation of the form

$$W=\alpha+\beta\,l,$$

a linear equation connecting W and l for constant currents.

The resistance form of my equation (4) is

$$r=\frac{38{\cdot}88+2{\cdot}074\,l}{A}+\frac{11{\cdot}66+10{\cdot}54\,l}{A^2}, \quad . \quad . \quad (6)$$

and making A constant in this, we get an equation of the form

$$r=a+b\,l,$$

where $$a=\frac{38{\cdot}88}{A}+\frac{11{\cdot}66}{A^2}$$

and $$b=\frac{2{\cdot}074}{A}+\frac{10{\cdot}54}{A^2}.$$

Now Edlund concluded from the results of his experiments that a and b both diminished as the current increased (p. 636, *The Electrician*, September 13th), and this is borne out by the above values for a and b; but he also thought that a varied inversely as the current, which was not exactly correct, but only nearly so for all but small currents, for unless A were very small in the above value for a, the term $\frac{11{\cdot}66}{A^2}$ would be small compared with $\frac{38{\cdot}88}{A}$.

Further, that the values which Edlund found for $a\,A$ were not constant, as they would be if a varied inversely as A, but in every instance but one showed a decrease as the current increased, is very easily seen from the following table, which gives the results Edlund obtained from his experiments with arcs with carbon electrodes:—

Table XI.—*Results obtained by Edlund.*

Numbers proportional to A.	Numbers proportional to a A.	Series of experiments.
1·2387	0·3239	1
1·0176	8·3416	„
0·6661	0·3336	„
1·1139	6·69	2
0·9435	6·877	„
0·9618	6·34	3
0·7738	6·48	„
1·3270	4 45	4
0·9827	5·21	„

The experiments of one series must not be compared with those of another, for each was carried out under different circumstances. But a comparison of those in each series will show that, except for one in the first series, the product $a\,A$ increases as the current A diminishes, which is exactly what would follow from my value of $a\,A$, viz.:—

$$a\,A=38{\cdot}88+\frac{11{\cdot}66}{A}.$$

Hence deviations which Edlund mistook for errors of observation were evidently caused by the presence of the term corresponding with $\frac{11{\cdot}66}{A}$ in the value of $a\,A$, and what Edlund did not notice was that with one exception all his errors were *in the same direction.* Thus the conclusion to be drawn from my equation (4) with regard to $a\,A$, which Edlund called the back E.M.F. of the arc, is more in harmony with the results of his experiments than his own conclusion was.

It is hardly necessary to enter into Edlund's theoretical reasons for supposing the term $a\,A$ to be independent of the current, since his own results really proved that it was not so.

To show the fallacy of his theory that, with a generator of constant E.M.F., the total power expended in the arc was proportional to the current, I need only point out that, if it were so, A V would be equal to $k\,A$, where k is a constant, or V would be a constant for all currents.

In the experiments used by Frölich there was naturally no sort of order (p. 636, *The Electrician*, September 13th). Only in two cases were more than two currents employed with the same length of arc, and in no case was the same current used with more than two lengths of arc; thus it is impossible to construct a complete equation from them. Fortunately, however, several currents were used with an arc of 2mm., and by calculating the power expended from the numbers given for currents and P.Ds., I was able to plot the curve connecting watts and amperes for length of arc 2mm., and found it to be a straight line, as it should be according to the second law upon which my equation was founded.

The equation to this straight line obtained from the experiments used by Frölich was

$$W=40{\cdot}25\,A+68{\cdot}25,$$

from which we get the P.D. in volts,

$$V=40{\cdot}25+\frac{68{\cdot}25}{A}.$$

Table XII. shows the value of the P.D. for each current quoted by Frölich for the 2mm. arc, and the value calculated from the preceding equation.

Table XII.—*Results used by Frölich.*

Current in amperes.	From experiment.	From equation.
27·4	42·7	42·75
11·6	46·3	46·13
8·39	50·1	48·38
7·67	47·1	49·15
6·92	50·1	50·11

The general agreement of the values for V obtained by experiment and calculation is striking, considering that different pairs of carbons were used by different people in obtaining the experimental results, and this agreement renders it quite certain that V and A are connected by an equation of the form I have given.

Frölich's statement, therefore, that the P.D. between the carbons was independent of the current, and that the true equation was

$$V=m+n\,l,$$

where m and n were constant *for all currents*, was indeed astonishing, and still more so was the fact of his having given values for m and n—viz., 39 and 1·8, and having asserted that the equation

$$V=39+1{\cdot}8\,l$$

was true for all currents up to 100 amperes. For, to take only the numbers given in Table XII., which are for length of arc 2mm., his formula would give

$$V=42{\cdot}6 \text{ volts}$$

for all the currents, whereas 42·7 volts is the smallest P.D. for the largest current, and the P.D. for the smallest current is 50 volts, or 7½ volts greater than the P.D. as calculated by Frölich. Such discrepancies as these, however, he dismissed as errors of observation, and he, like Edlund, did not notice that all or nearly all these apparent errors of observation *were in the same direction.*

Since Frölich's equation for P.D. did not really express the results of the experiments upon which he founded it, it is unnecessary to dwell upon his equations for apparent resistance and power, which he deduced from that for P.D., and which, equally with it, were entirely at variance with the experimental results. Indeed, the only suggestion made by

Digitized by Google

Frölich in his Paper that appears likely to prove true was that the cross-section of the arc was directly proportional to the current.

The first systematic attempt to find the P.Ds. that would send a given constant current through many lengths of arc was made by Peukert (p. 637, *The Electrician*, September 13th), who first, after Edlund, saw the value of eliminating one of the three variables, P.D., current and length of arc.

Having measured the P.Ds. corresponding with his various currents and lengths of arc, Peukert plotted curves connecting apparent resistance and length of arc, and found them to be straight lines. He gave the equations to these lines, and from them I have constructed the following equations connecting *power* and length of arc for each of the currents he used, by

From Peukert's Experiments.

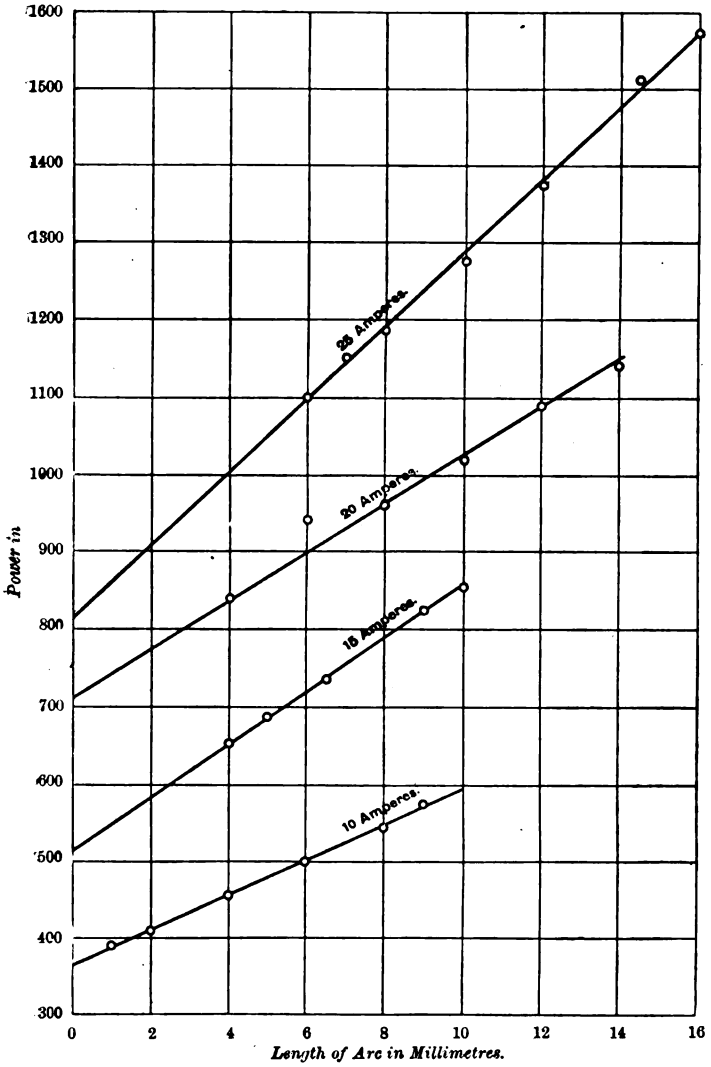

Fig. 42.—Watts and Length of Arc for Different Constant Currents.

multiplying each equation through by the square of the current which corresponded with it :—

For $A = 10$ amperes, $W = 366 + 23\,l$.
„ $A = 15$ „ $W = 517 + 33{\cdot}75\,l$.
„ $A = 20$ „ $W = 720 + 32\,l$.
„ $A = 25$ „ $W = 812{\cdot}3 + 46{\cdot}87\,l$.

These, when plotted, give the four straight lines seen in Fig. 42, and it is clear that the line for 20 amperes is wrong, as it does not make a large enough angle with the axis of l. Hence the coefficient of l, which determines the slope of the line, must be too small in the power equation for 20 amperes. And that that is the case is seen from an examination of these four power equations, for while the coefficients of l for 10, 15 and 25 amperes increase as the current increases, that for 20 amperes—viz., 32—is less than 33·75, the coefficient for 15 amperes.

Consequently the coefficient of l in Peukert's own resistance equation for 20 amperes—viz., 0·08—must also be too small. But this he was not able to detect, since it lay between 0·15 and 0·075, the coefficients of l for 15 and 25 amperes respectively. The above power equations which I have calculated from his resistance equations make us sure, however, that there was something wrong, either in Peukert's apparatus or with his observations for the current of 20 amperes.

If from the four lines connecting power and length of arc for each current we take the number of watts corresponding with length of arc 10mm., and plot them with their respective currents, and also the number of watts corresponding with length of arc 0mm., and plot them with their respective currents, we find, as was to be expected from what has gone before, that the values follow the second of the four laws I have formulated, and that the curves are straight lines (Fig. 43).

The equations to these lines are

$$W_{10} = 46{\cdot}22\,A + 129{\cdot}42,$$
$$W_0 = 30\,A + 66.$$

Substituting these values for W_{10} and W_0 in the equation

$$\frac{W - W_0}{l} = \frac{W_{10} - W_0}{10},$$

which is the equation to any one of the lines in Fig. 42 connecting power with length of arc for a constant current, we find the equation

$$W = 30\,A + 66 + (1{\cdot}622\,A + 6{\cdot}342)\,l,$$

representing the connection between watts, length of arc and current, when all three may vary.

Dividing throughout by A, we have—

$$V = 30 + 1{\cdot}622\,l + \frac{66 + 6{\cdot}342\,l}{A},$$

which is the general equation which Peukert might have obtained to express the results of his own experiments had he seen the importance of obtaining and employing the power equations.

In order to test how nearly the equation given above really expresses Peukert's results, we may divide by A, and obtain the equation for the apparent resistance of the arc :—

$$r = \frac{30 + 1{\cdot}622\,l}{A} + \frac{66 + 6{\cdot}342\,l}{A^2}.$$

If we now give A the values respectively of 10, 15, 20 and 25 amperes in this resistance equation, we find the equations on the right-hand side of Table XIII. :—

Table XIII.—*From Peukert's Results.*

Current in amperes.	Peukert's equations.	From the above general equation.
10	$r = 3{\cdot}66 + 0{\cdot}23\,l$	$r = 3{\cdot}66 + 0{\cdot}23\,l$
15	$r = 2{\cdot}3 + 0{\cdot}15\,l$	$r = 2{\cdot}29 + 0{\cdot}14\,l$
20	$r = 1{\cdot}3 + 0{\cdot}08\,l$	$r = 1{\cdot}67 + 0{\cdot}096\,l$
25	$r = 1{\cdot}3 + 0{\cdot}075\,l$	$r = 1{\cdot}31 + 0{\cdot}075\,l$

Comparing the two sets of equations, we find a striking agreement in the case of the first, second and fourth equations, while the third, which differs from that given by Peukert, expresses the result which Peukert would have obtained if he had not, as already explained, made an error when testing with 20 amperes.

Since the above equation expressing the results of Peukert's experiments is of exactly the same form as my equation (4), one would expect that his results would not only follow the two first laws upon which equation (4) was founded, but that they would follow the whole four of those laws, and such is, in fact, the case.

For, if we put $A = -\dfrac{6{\cdot}342}{1{\cdot}622}$ in the power equation for Peukert's results, the coefficient of l disappears, and we have

$$W = 66 - 30 \times \frac{6{\cdot}342}{1{\cdot}622}.$$

Hence $A = -3{\cdot}91$
and $W = -51{\cdot}3$

Digitized by Google

are the co-ordinates of the point where all the lines connecting power and current for the various constant lengths of arc meet.

Similarly putting $l = -\frac{30}{1\cdot622}$, the coefficient of A disappears, and we get

$$l = -18\cdot5$$

and $$W = -51\cdot3$$

as the co-ordinates of the point at which all the lines connecting power and length of arc for the various constant currents meet.

Thus the *results* of Peukert's experiments completely fulfil all the four laws upon which my equation (4) is founded and are, therefore, completely in harmony with my *results.* I shall now show that where the *conclusions* he drew differ from mine, his own experiments prove him to be mistaken.

The resistance form of the general equation which I have deduced from Peukert's results may be put in the form

$$r = a + b\,l,$$

where $$a = \frac{30}{A} + \frac{66}{A^2}$$

and $$b = \frac{1\cdot622}{A} + \frac{6\cdot342}{A^2}.$$

The second term in the value for a is never very big compared with the first term with the currents Peukert used, for the numerator of the second term is only about twice as great as the numerator of the first, whereas the denominator of the second is at least ten times as great as the denominator of the first. Hence it is not very surprising that Peukert followed Edlund in asserting that a varied inversely as the current. Yet his own results show that this is not the case, for if it were, a A would be a constant, whereas multiplying the first term in each of Peukert's own equations by the corresponding current, the resulting numbers are 36·6, 34·5, 36, and 32·5, which go in descending order as the current increases, as my equation indicates that they should. The only exception is in the equation for 20 amperes, which I have already shown to be wrong. He saw, however, that b diminished more rapidly than the current, and this he was able to do because, on examining the expression I have given above for b, we see that the coefficient of the second term is four times as great as that of the first term. Hence even with fairly large currents the second term is not negligible compared with the first, and consequently Peukert was able to find an approximate law for the value of b, for which the last equation gives the full and exact law.

From the experimental observations published by Messrs. Cross and Shepard (p. 637, *The Electrician*, September 13th) I have plotted curves connecting the apparent resistance and length of the silent arc for each current they used, and have found an equation to each of these lines which fits their results rather more closely than those which they themselves gave. From these slightly more accurate equations I constructed the following equations connecting *power* and length of arc, by multiplying each equation by the square of the corresponding current, just as I had done with Peukert's equations, and found :—

For $A = 5\cdot04$ amperes, $W = 201\cdot3 + 13\cdot34\,l$
„ $A = 7\cdot0$ „ $W = 273\cdot0 + 13\cdot6\,l$
„ $A = 7\cdot92$ „ $W = 310\cdot0 + 16\cdot24\,l$
„ $A = 10\cdot04$ „ $W = 380\cdot0 + 18\cdot94\,l$

These, when plotted, give the straight lines in Fig. 44, and, like Peukert's curves, they show that one line—the line for 7 amperes—has the wrong slope, as may also be seen from the power equations. For evidently the coefficient of l for 7 amperes is too near in value to the coefficient for 5·04 amperes, and not near enough to that for 7·92 amperes.

Taking the number of watts corresponding with length of arc 10 from each of the four lines in Fig. 44, and plotting them with their respective currents, we obtain the upper line in Fig. 45, and plotting the watts for length of arc 0 with their corresponding currents, we get the lower line.

That these are straight lines is very evident, although one point of each is off the line, and it is thus evident that Cross and Shepard's results, as well as Peukert's, follow the second of my four laws. Fig. 44 shows that they also follow the first.

The equations to the two lines in Fig. 45 are

$$W_{10} = 48\,A + 93\cdot6,$$
$$W_0 = 37\,A + 14\cdot8.$$

Substituting these values for W_{10} and W_0 in the equation

$$\frac{W - W_0}{l} = \frac{W_{10} - W_0}{10},$$

which is the equation to any one of the lines in Fig. 44, we have

$$W = 37\,A + 14\cdot8 + (1\cdot1\,A + 7\cdot88)\,l$$

as the general equation connecting the power, current and length of arc, when any of the three may vary, for Cross and Shepard's results.

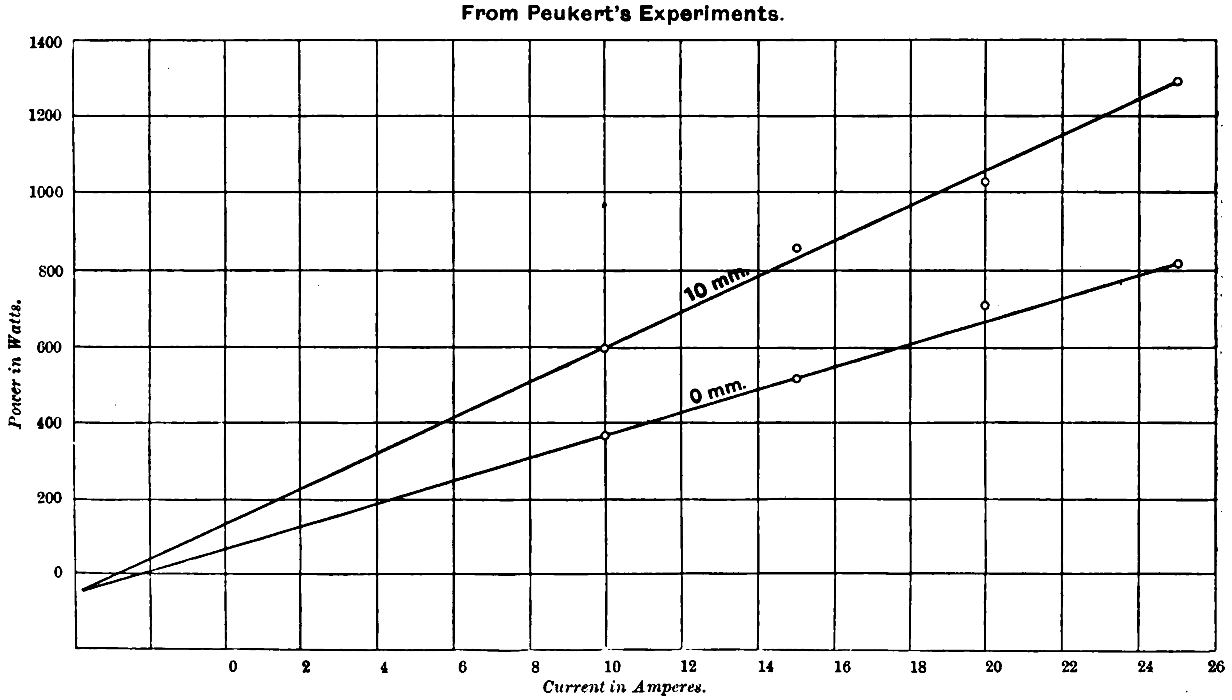

FIG. 43.—Watts and Current for Arcs of 10mm. and 0mm.

Digitized by Google

Dividing by A we have

$$V = 37 + 1{\cdot}1\,l + \frac{14{\cdot}8 + 7{\cdot}88\,l}{A},$$

as the general equation connecting P.D., length of arc and current for the Cross and Shepard results.

If now we divide this last equation throughout by A we get

$$r = \frac{37}{A} + \frac{14{\cdot}8}{A^2} + \left(\frac{1{\cdot}1}{A} + \frac{7{\cdot}88}{A^2}\right) l$$

for the resistance equation, and giving A the values of the currents they used, we get the equations on the right-hand side of the following table:—

Table XIV.—*From Cross and Shepard's Results.*

Current in amperes.	From experiments.	From general equation.
5·04	$r = 7{\cdot}925 + 0{\cdot}525\,l$	$r = 7{\cdot}923 + 0{\cdot}528\,l$
7·0	$r = 5{\cdot}57 + 0{\cdot}277\,l$	$r = 5{\cdot}59 + 0{\cdot}317\,l$
7·92	$r = 4{\cdot}94 + 0{\cdot}259\,l$	$r = 4{\cdot}91 + 0{\cdot}264\,l$
10·04	$r = 3{\cdot}77 + 0{\cdot}188\,l$	$r = 3{\cdot}83 + 0{\cdot}187\,l$

The two sets of equations do not agree as well as those obtained from Peukert's results, because the range of current

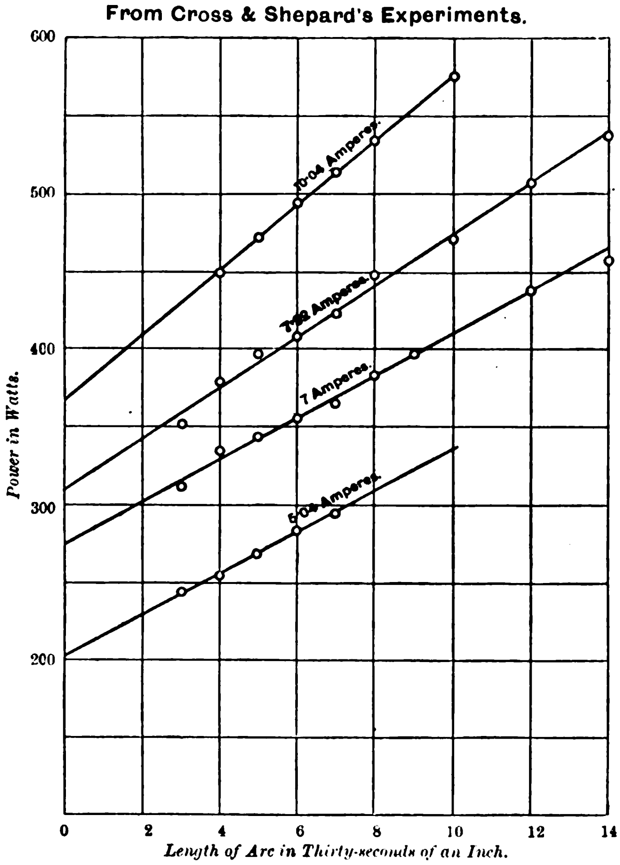

FIG. 44.—Watts and Length of Arc for Different Constant Currents.

was so much smaller, and the exact course of the lines was, therefore, much more difficult to obtain, but they agree quite closely enough to show that my general equation does really give the connection between the three variables, even if the straightness of the lines in Figs. 44 and 45 had not already shown it.

The co-ordinates of the point at which the lines in Fig. 44 meet may be found in the same way as similar co-ordinates have been found previously. They are—

$$A = -7{\cdot}16$$

and $$W = -250{\cdot}12.$$

Similarly, the co-ordinates of the point at which the lines in Fig. 45 meet are

$$l = -33{\cdot}64$$

and $$W = -250{\cdot}12.$$

. Thus, Messrs. Cross and Shepard's results also follow the four laws upon which my equation is founded.

Besides calculating the values of the constants a and b in the resistance equation $r = a + b\,l$, Messrs. Cross and Shepard gave the value of the product a A for each of the currents used. As already mentioned, Edlund, Frölich and Peukert had considered that this product was on the whole a constant, and this constancy Edlund regarded as proving the existence of a constant back E.M.F. in the arc. Messrs. Cross and Shepard, however, showed that the product diminished as the current increased; they did not give the actual law of variation, which, in my remarks on Peukert's equations, I have pointed out is

$$a\,A = \text{constant} + \frac{\text{constant}}{A};$$

but to them is due the credit of first noticing that as a increased a A diminished, and also of pointing out that Peukert's equations, when correctly interpreted, led to the same conclusion.

The formula given by Prof. Silvanus Thompson in 1892 (p. 638, *The Electrician*, September 13th),

$$V = m + n\frac{l}{A},$$

where m might vary from 35 to 39 volts, and n might have values from 8 to 18, was the first real attempt to find an equation connecting the P.D., current and length of the arc when all three varied.

Multiplying his equation throughout by A, we have the equation for the power

$$W = m\,A + n\,l,$$

which gives straight lines for power and length of arc with constant currents, and straight lines for power and current with constant lengths of arc.

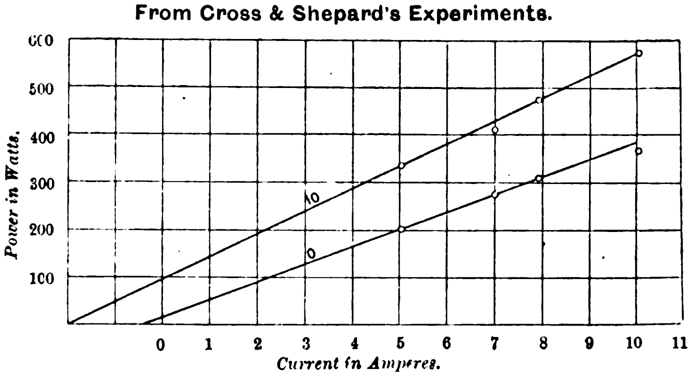

FIG. 45.—Watts and Current for Arcs of 10 thirty-seconds of an inch and 0 thirty-seconds of an inch.

Thus far, then, Prof. Thompson's formula agrees with mine, and when we consider that it was only put forward as an approximate formula founded on no special experiments, we must see that it needed great insight into the true nature of the connection between the variables to unravel that connection so far.

If, however, we compare the above equation more in detail with mine, we find that there are radical differences between them.

For my power equation (5)

$$W = 11{\cdot}66 + 38{\cdot}88\,A + 10{\cdot}54\,l + 2{\cdot}074\,A\,l$$

contains a term independent of both A and l, and a term containing the product of A and l, whereas Prof. Thompson's power equation,

$$W = m\,A + n\,l,$$

contains neither of these.

The term 11·66, which is independent of both current and length of arc, in my power equation shows that there must be a certain minimum power expended in the arc, whatever its length and the current flowing through it; for however small A and l may be, W can never be less than 11·66. This minimum power is not indicated in Prof. Thompson's equation. Its physical meaning I have not yet fathomed, but it appears to be the part of the power that varies most with different sorts

Digitized by Google

of carbons, for in the equation from Peukert's experiments the term which is independent of A and l is 66, or more than five times as great as in my equation, and in Cross and Shepard's it is 14 8, whereas all the other three constants have very much more nearly the same value in the three equations.

The difference introduced by the presence of the term involving the product $A\,l$ is best seen by considering the equations for the P.D. Prof. Thompson's equation may be written

$$(V-m)\,A = n\,l.$$

Mine, when put into the same form, becomes

$$\{V-(38{\cdot}88+2{\cdot}074\,l)\}\,A = 11{\cdot}66+10{\cdot}54\,l.$$

Prof. Thompson stated at the meeting of the British Association in Ipswich last month that his equation was founded on experiments made by different students at different times, with different carbons, and with different currents produced by different generators, and that the variations of m and n appeared to depend upon some of these differences, but he could not quite tell which.

Under these circumstances it is difficult to know whether his n is to be regarded as constant for a fixed length of arc or not. Supposing that it is, however, then his equation agrees with mine in representing a family of rectangular hyperbolas having one asymptote in common—viz., the axis along which P.D. is measured. The other asymptote, which is parallel to the axis of current, is distant from that axis by a length equal to m in Prof. Thompson's equation, and to $38{\cdot}88+2{\cdot}074\,l$ in mine, where the unit of length is that which has been arbitrarily taken to represent a volt. m is stated in Dr. Thompson's equation to vary between 35 and 39 volts; hence, whatever the length of the arc, the horizontal asymptotes must all be between these limits, or practically the rectangular hyperbolas in Fig. 33, page 419, *The Electrician*, July 26th, ought, according to his equation, all to have nearly the same horizontal asymptote. This is clearly not the case, and my equation above shows that with the carbons I used the distance of this asymptote from the axis of current varies between 38·88 volts for l equal to 0mm, and 59·62 volts for l equal to 10mm.

Hence the m in Prof. Thompson's equation, instead of having a nearly constant value of 35 to 39 volts, varies in reality between wide limits as the length of the arc is varied.

Another result of the absence of the two terms we have been discussing in Prof. Thompson's equation is that neither of the two sets of lines represented by his power equations meet at a point, for there is no way of obtaining an equation between W and A which shall be independent of l, or an equation between W and l which shall be independent of A, except by making n in the first case and m in the second case equal to 0. But neither m nor n can equal 0, for we know the limits of their values, therefore neither of the sets of lines can meet at a point.

The Paper of Messrs. Duncan, Rowland and Todd's, from which I have already quoted, begins with a list of the equations used by other experimenters, among them

$$V = m + b\,A\,l,$$

attributed to Edlund, and

$$V = a\,A + b\,A\,l,$$

attributed to Cross and Shepard.

What Edlund, and also Cross and Shepard, really proved, however, was that for any particular value of the current the equation connecting the apparent resistance of the arc with the length was

$$r = a + b\,l,$$

where a and b were constants for the particular current. But when the current was increased they showed that a and b both diminished; therefore, while it is perfectly correct to add together $a_1\,A_1$ and $b_1\,A_1\,l_1$, in order to find V_1, the P.D. between the carbons for a length l_1 and for a current A_1, for which the values of a and b are a_1 and b_1, it is entirely wrong to attribute to Edlund, or to Cross and Shepard, as Messrs. Duncan, Rowland and Todd have done, the general equation

$$V = a\,A + b\,A\,l,$$

where a and b appear to be constant for all values of A and of l.

It seems to me desirable to draw attention to this correction, because the version of Edlund's and of Cross and Shepard's equations given by Messrs. Duncan, Rowland and Todd have been subsequently quoted as correct by others, who have, I presume, not referred to the original publications.

Messrs. Duncan, Rowland and Todd gave the values of the P.D. and current obtained experimentally for one length of arc ⅛in. long obtained with cored carbons. On calculating from these the values of the power, I find that the curve connecting power and current is very nearly a straight line, and therefore very nearly fulfils my second law; but whether it would, but for errors of observation, have completely fulfilled it, it is impossible say. I have before mentioned that for *cored* carbons the curve connecting power and current was only *almost* a straight line; it will require further experiment to prove whether it should be quite straight or not.

The equation to the straight line obtained from Duncan, Rowland and Todd's experiments is

$$W = 40{\cdot}6\,A + 84{\cdot}17;$$

therefore for the P.D. we have

$$V = 40{\cdot}6 + \frac{84{\cdot}17}{A}.$$

In Table XV. is given a comparison of the values of the P.D. obtained experimentally by Messrs. Duncan, Rowland and Todd, and the values calculated from the preceding equation.

Table XV.—*From Duncan, Rowland and Todd's Results.*

Current in amperes.	P.D. in volts.	
	From experiment.	From the equation.
3·1	65·0	67·8
4·6	58·5	58·9
6·15	54·8	54·3
7·7	52·5	51·5
8·0	52·0	51·1
9·82	49·2	49·2
11·26	47·5	48·1
12·75	46·5	47·2

With the exception of the first P.D., which is on the steepest part of the curve connecting P.D. with current, where a very small error in the current would make a considerable difference in the P.D., none of the P.Ds. calculated from the equation differ by more than one volt from those obtained by experiment, and only one differs by as much as that. Thus it seems highly probable that even for cored carbons a linear law does really connect power and current for a constant length of arc.

It is, of course, impossible to tell from the table given whether the first law connecting power and length of arc for constant currents is borne out by Duncan, Rowland and Todd's results, for they only gave the results for one length of arc. In any case, however, it was amply proved by the experiments of Prof. Ayrton's students with cored carbons, which I have published in *The Electrician*, that the curve representing the connection between power and length of arc for constant current is *not* a straight line for cored carbons.

Messrs. Duncan, Rowland and Todd gave as the equation connecting V, l and A,

$$V = m + f(l)\,f(A) + n\,f'(l)\,f'(A),$$

but, as the form of the functions was not stated, it is, of course, impossible to make a comparison between that equation and the one at which I have arrived.

To sum up then, it appears that wherever experimenters have given numbers which allow of their being tested by an equation of the form

$$V = a + b\,l + \frac{c + d\,l}{A}$$

they are found to satisfy such an equation with remarkable accuracy. Hence, so far from the different experimenters on the arc having all obtained different results, as has hitherto been supposed, their results present a striking unanimity when viewed by the light of the wider generalisations in which I have been able to present them.

(*To be continued.*)

THE COLLINSON AMPERE-HOUR METER.

The problem of a cheap yet efficient ampere-hour meter, for use in electric supply systems, has been attacked by Mr. P. Collinson, for some years the chief engineer at the Morecambe electric supply station. The accompanying illustrations depict the instrument which is the outcome of his researches. Mr. Collinson has adopted a principle of action in his meter with which many before him have tried and failed, and it will be a highly creditable result, if he succeeds in making the instrument a commercial success. That a cheap meter is a

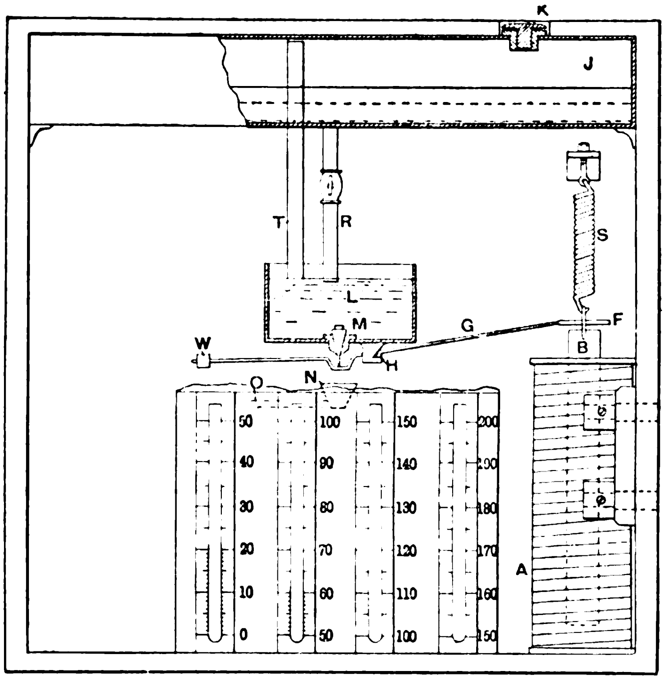

Fig. 1.—Collinson Ampere-Hour Meter: Vertical Section.

great desideratum it goes without saying; and we understand that Mr. Collinson intends to supply his for less than £3. The principle to which we have just referred, is the measurement of electric quantity in terms of the weight or volume of a liquid permitted to pass through a throttled passage, the amount of constriction depending upon the electric current.

Fig. 1 represents a vertical section of a small meter, designed for a range of current of from 0·3 to 5·0 amperes, at an electric pressure of 115 volts. Fig. 2 shows a plan of the liquid

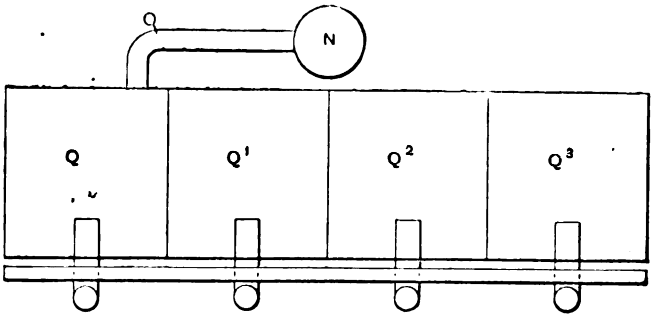

Fig. 2.—Collinson Ampere-Hour Meter: Plan of Liquid Storing Tank.

storing tanks. A solenoid, A (Fig. 1), in the circuit of the current to be measured, has within it a soft-iron core, B, suspended by a link from the coil spring S. In the link, and free to move vertically, is the soft-iron armature F, attached to the end of the lever G, which is suspended at the fulcrum H. Normal equilibrium is obtained by the counterpoise W. There is an air-tight storage tank, J, with a filling hole and screwed cap at K. The open cistern, L, is fitted at the bottom with an outlet valve at M, below which there is a funnel, N, connected by a pipe, O, to the first of a series of tanks, Q (shown in plan in Fig. 2), for collecting and storing the liquid. The reservoir tank, J, is provided with two tubes, R and T, for maintaining a constant level of liquid in the cistern L.

The action of the minimum current (0·3 ampere), though not sufficient to cause movement of the core B, yet magnetises it, and causes the armature F to be drawn down, thus slightly depressing the lever G, and opening to a small extent the orifice, by which a slight discharge of liquid takes place. An increase of current causes the core B to be drawn into the solenoid, and thereby opens the valve M wider, allowing a greater escape of liquid in proportion to the current. The series of storing tanks are arranged that each will overflow into the next; and the level of the liquid in each is indicated on a gauge. The scales behind the gauges are graduated to read in Board of Trade units. The particular meter shown is designed to register at the rate of 600 watts. Meters ranging to 50 amperes are contained in wooden cases measuring 12in. × 12in. × 6in.; and it is claimed they will run for six months without attention.

THE ELECTROLYSIS OF MILK.

In a somewhat lengthy Paper recently sent us by Mr. C. E. S. Phillips, the author, after referring to some of the tests adopted for ascertaining the purity of milk, proceeds to describe experiments undertaken to discover whether electrolysis would offer a more expeditious and reliable method than those in use. On electrolysing a sample of milk between platinum electrodes, the anode became coated with a white, spongy-looking material which increased until so thick upon the plate that it ultimately became disengaged and floated to the surface of the milk; it was observed on making experiments in this way that the white deposit consisted principally of a mixture of caseine and fat, that the milk gave off a characteristic odour during the electrolysis, and it was found to be slightly alkaline after the operation. The liberated caseine floating upon the milk seemed to show that owing to alkalinity of the solution it had become insoluble; it was, however, evidently due to the lifting power of the gas bubbles clinging to it. By continuing the electrolysis further it was possible to extract practically all the solids from the milk used (30 cubic cm.), leaving a transparent solution behind; at the same time no appreciable deposit of any kind took place at the negative electrode. Tests made with litmus paper during electrolysis showed that the action was extremely local; it was, however, noticed that the froth on the negative electrode produced by a too rapid electrolysis was strongly alkaline. The formation of caseine on the positive electrode was then studied in a miniature cell under the microscope. On making the circuit bubbles of gas appeared upon each electrode, more of course at the negative one, but at the anode a yellowish deposit grew and spread uniformly out towards the opposite electrode. A dark ridge was built up about equidistant all along the electrode, and became more definite till the band widened out on either side, and concentrated at a point immediately opposite the cathode. Very peculiar movements could be made to take place in this band by making and breaking the circuit rapidly. Photographs showing these changes are given by the author. A drop of litmus used to stain the milk showed that an acid and an alkali were formed at the anode and cathode respectively, evidently accounting for the deposition of caseine at the former. The action would appear to be similar to that which takes place when milk is exposed to air for some days; lactic acid is formed, which throws down the caseine. By electrolysis, however, the action can be started and stopped as desired, so that any portion or all of the caseine can be removed from the milk. Next a small vessel was divided into three compartments by means of two porous partitions, and the effects recently described by M. Andréoli were tried. About 10 cubic cm. of milk were poured into the centre division, while the anode and cathode compartments contained a solution of sodium chloride. On the passage of the current a deposit was formed in the centre compartment on the side of the partition separating it from the anode. When all three compartments contained milk, the deposit occurred on the sides of both partitions furthest from the anode. Under these circumstances it seems that an action takes place in the milk in the centre compartment. No deposit took place upon metallic plates immersed in the milk in either case. Some experiments upon the preservation of milk by means of this electrical withdrawal of a portion of its caseine were made, but with no success so far. Mr. Swinburne mentions, however, that milk can be sterilised electrolytically (*The Electrician*, Vol. XXIX., p. 391). In conclusion, the author states that platinum is the most suitable material to use for electrodes in the electrolysis of milk, as the lactic acid formed attacks most other metals. Aluminium can, however, be used in certain cases for the positive electrode, but it is eventually dissolved, and consequently of little use for quantitative work.

STEEL-PLATE PORTRAITS.

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; and William Sturgeon have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

PROGRESS OF THE POSTAL TELEGRAPH SERVICE.

Last week we had to comment upon a feature of the POSTMASTER-GENERAL'S Annual Report as unpleasing as it was novel. Another, equally novel, but far more interesting, portion of that Report calls for further observations to-day. We refer to the "Historical Outline of the Telegraph Service since 1870" contained on page 33, and reproduced at length in our present issue. This memoir appears as a fitting landmark in the progress of telegraphy under Post Office management for the past quarter of a century; and its compilation, at once lucid and compact, is in most respects worthy the occasion. The historical survey is taken up principally with what may be called the traffic returns of the period, and the engineering department; a very natural preponderance of attention being given to these items, which reflect the greatest credit on the management. On the financial side of the subject comparatively little is said, but quite sufficient to indicate that more—very much more—remains unexplained. Regarded as a public servant the Telegraphs is all that could be desired, and its achievements are set forth with evident confidence and pride. Not so regarded as a financial undertaking; and the perfect frankness, not to say complacence, with which its failure in this respect is announced, suggests the reflection that while success in one direction is a subject of general congratulation, failure in the other direction is a matter of indifference. The account is supposed to emanate from the head of the Post Office; we cannot help wondering whether the same philosophical tone would have characterised the financial part of it had it been written by the head of the Telegraph Department.

As to the splendid career of the Telegraphs, apart from its shortcomings as a revenue-earning concern, there can be no question. The enormous outlay on wires and plant during the first few years after 1870, although considered extravagant at the

Digitized by Google

time, proved to be none too great for the overwhelming growth of business with the increased facilities which these extensions afforded. In a very short time the traffic had doubled, and just prior to the reduction of the tariff to 6d. in 1885 the number of telegrams had risen from 7,000,000, at which it stood at the time of the transfer, to no less than 33,000,000. The outlay, having been on a far-seeing and liberal scale in the first instance, had not increased in nearly the same ratio, the additional work being disposed of easily by means of improvements in electrical methods and appliances. Without these improvements, it may be confidently said that no reduction of rates, with its consequent burden of messages, would have been possible. The effect of lowering the initial charge from 1s. to 6d. was to swell the number of messages from 33,000,000 to almost double in less than four years; and the growth has gone on increasing until now, when the annual total stands at about 72,000,000 per annum, or ten times what it was when the State took over the work. No other country in Europe makes such extensive use of the telegraph, and we have yet to learn that these magnificent figures are exceeded in the United States. If the efficiency of the Telegraphs may be measured by the use that is made of it, nowhere is it so trustworthy as in the British Isles.

But this does not by any means represent the aggregate amount of telegraphing crowded on to the wires in this country, where the Press tariff is so low as to attract no fewer than 650,000,000 words annually. The aggregate for all other messages is only 970,000,000, so that the Press alone appropriates two-fifths of the whole traffic, and as the average length of each Press message is 120 words, whilst that of an ordinary message is less than 15, it will be seen that the nominal total number of telegrams is no criterion of the actual work performed. Taking this fact into account, the business of the Telegraphs has increased since 1870, not ten-fold, as is claimed, but more probably fifteen-fold. The number of offices has increased rather more than three-fold, and the mileage of wire less than four-fold. Instruments now number 26,000, against 4,000 at the beginning of the period, but this increase may be set down largely to a vast augmentation in the number of small offices and minor circuits, not wholly to increase of work.

These last-named figures bring us to the most striking feature of the case—namely, the comparatively small expenditure on material and appliances for such a rapid and enormous growth of business. The official mind appears to be fully alive to this fact, giving ungrudging praise to the Technical Department of the Telegraph Service for its enlightened policy in accepting inventions and new ideas from outside sources, and for its zeal and ingenuity in effecting improvements on its own account. But for the spirit prevailing in this Department, differing, by all accounts, from every other State department, the Service must either have utterly broken down, or a vast outlay have been incurred in the multiplication of wires and apparatus. Instead of this, by accepting the best devices forthcoming from America, and by adapting them to the climatic conditions of this country, by unremitting labour in perfecting the fast-speed instruments of English origin, and by supplementing them with repeaters of original design, circuits which formerly were worked at the rate of 50 words a minute can now dispose of 500; and each wire which normally only carries one message at a time can now at pleasure be made to convey four and even six at the same time. Making every allowance for the costliness of the appliances needed for these operations, it is hardly an exaggeration to say that every increase of traffic is met, not by fresh demands on the exchequer, but by the extended application of electrical devices under the guidance of the technical officers of the Department.

It is perhaps necessary to emphasise this statement, because a little further on the results are ascribed—probably by a slip of the pen – to the "officers of the Post Office." One might, with just as little truth, ascribe the failure of the Telegraphs financially to the engineering staff. In reality the two departments appear to be now as widely apart as ever they were, the officers in one section being all telegraphists by profession, whilst in the other they are all post-office officials. For the efficient working of the Telegraph Service the former are primarily responsible, and they have reason to be proud of their achievements. For the financial failure of the Service the responsibility, such as it is, must always rest with the Post Office. We have spoken of the head of the Telegraph Service; but there is no such head, or, at all events, none that is at once responsible for and solicitous of the reputation of the Telegraphs as distinct from that of the Post Office. If such an officer existed he would not admit that the Telegraphs cannot pay; he would probably deny that it does not pay. More than one Postmaster-General has declared that it is impossible to separate the accounts of the two services on anything approaching equitable lines; and so long as the Telegraph Service is without any representative on the postal staff, who have the sole control of its finances, so long will the public be dissatisfied with the excuses put forward for the financial deficits proclaimed year after year in the Telegraphs balance sheet. It may be that the figures represent the real facts; but it would be more satisfactory if someone with an interest in the Telegraph Service had a hand in preparing them. In any case, supposing them to be fair and true, the responsibility must, as we have said, rest with the Post Office. Nobody but the Post Office would have so long endured the imposition of such absurdly generous Press rates, or of railway free messages, or the drain upon telegraph revenue due to private telephonic enterprise. A great public department may have its own reasons for pliability in such important particulars, but that is only an argument for assimilating the two services in reality as well as in name. So long as they are kept separate so long will the Post Office proper be tempted to swell its reputation for liberal concessions to the public at the expense of a service in which it has no personal or historic interests to preserve or safeguard against unreasonable and unprofitable concessions.

REVIEWS.

Motive Powers and their Practical Selection. By REGINALD BOLTON. (London: Longmans, Green and Co. 1895.)

This little book consists mainly of a heterogeneous compilation of engineering data and details of practice, the professed purpose being to assist an ordinary or non-technical person in the selection of motive power for any class of work he may wish to accomplish. All the various sources of power, and the engines in which they are usefully developed, are considered; and about each one a quantity of more or less reliable and accurate information has been compiled. Nevertheless, we cannot consider that Mr. Bolton's book has successfully hit the mark at which he aimed. To the non-technical reader, it will be a composite mass of figures and statements; difficult to comprehend, and not infrequently misleading or absolutely incorrect. To the engineer it supplies no information which is not far better and more reliably given in the standard treatises with which he ought to be familiar. To that intermediate and unsatisfactory individual, the man whose little knowledge has reached the danger mark, such works as this may prove of some assis-

Digitized by Google

tance in the perpetration of *dilettante* and amateurish engineering; and it is often such people as those who belong to this class, who first of all do a job badly, and afterwards have to call in a professional engineer to help them out of their troubles and put things right. Let us seek to justify these criticisms by more direct reference to some of the contents of Mr. Bolton's book. Here is a quotation from an early chapter:—

"The conduction of the current over a wire involves a certain loss by friction, which must be allowed for, and of which tables are given, rendering elaborate calculation unnecessary."

Or again, describing secondary batteries, he writes:—

"They are boxes containing alternate frames or plates of various compositions, chiefly based on lead, which being immersed in dilute sulphuric acid, one set are decomposed by the action of the electric current and deposited upon the other."

It is a comfort to be told that "electricity is incapable of explosion of any kind"; but what does the statement mean? Or, what guide to the selection of motive power is disguised beneath the statement that "an electric motor is practically a dynamo reversed," which is all the description of these motors which we can find; unless, we are to couple this statement to the assertion that "a dynamo is extremely simple to manage." The voltages which do not give dangerous shocks are "110, 105, 100, 85, 65, 60 and 50," which to know may be useful in its way.

We find, however, a considerable amount of accurate information in this book; much of which might be gleaned and sifted out by a student possessing sufficient experience to enable him to distinguish between wheat and tares. The chapters on steam plant are particularly replete with such information, either in the form of tables or of general statements.

The Practical Telephone Handbook and Guide to the Telephonic Exchange. By Joseph Poole, A.I.E.E. Second Edition. (London: Whittaker and Co. 1895).

An admirable idea of the equipment and operation of a telephone system, whether for but one or two subscribers or for a large multiple exchange, is to be derived from a perusal of this well-arranged and well-written little treatise. We can heartily recommend Mr. Poole's book to all who desire to receive an intelligent general instruction in the subject, and who wish not to be too much burdened with technical matters. A subscriber, for example, curious to learn something of the ins-and-outs of telephone work; a telephone employé, anxious to gain an elementary knowledge of the principles and working of the industry with which he is connected; or the student, or the amateur telephone maker; might with undoubted advantage peruse the pages of the volume before us. We are glad to find that very little space has been devoted to the ancient history of the subject; the chapter devoted to this being short, and happily destitute of many of the fossils which it is too often the custom to trot out in small manuals and elementary textbooks. No one but an antiquarian feels very keen interest in model ears made of pig's bladder and timber. The chapters describing the various transmitters and receivers now in common use are very well written; the material having been well chosen with a view to practical utility, and showing evidence of an acquaintance with practice in other countries than our own. By developing gradually the subject of switches and exchanges, and starting with the simplest arrangements of telephone circuits, the author brings his descriptions even of the complications of elaborate exchanges within the comprehension of a non-technical reader; and his descriptions are supplemented by a number of well-drawn illustrations, mostly of details drawn to scale. When the author tells us that "punning is very important, and should on no account be scamped," he is not referring to the vicious misuse of words, but is describing how an important operation in "outdoor construction" should be carried out; and the chapter which he devotes to this branch of his theme is full of practical advice and information. A short chapter is devoted to "Long-Distance Working," and contains some account of the induction trouble and its remedies. The author appears to put entire faith in the much-debated K.R. law. Since the issue of the first edition of this book, the practice of metallic-circuit working has been developed very extensively, and a chapter on this important extension of practice deals with the subject in a brief but clear and useful manner. The author expresses the view that "as electric lighting and electric traction are getting so general, it is becoming absolutely necessary to discard the earth return."

A First Book of Electricity and Magnetism. By W. Perren Maycock. Second Edition. Thoroughly revised, corrected, and greatly enlarged. (London: Whittaker and Co.)

The author has written this little book "for the use of elementary science and engineering students, and general readers," and it may be safely recommended to those for whom it is intended. We have no desire to make captious criticisms of a little manual which is so generally excellent, but we would suggest to the author that the Ewing molecular theory of magnetism and the researches of J. J. Thomson and others on the electrolysis of gases warrant a more exact explanation of the supposed cause of magnetic retentivity, and a more qualified statement as to the invariability of the sign of the atomic charge. Beginners, we have frequently observed, have a particular liking for complicated mnemonic rules, giving the direction of the current in a wire when the deflection of a compass needle is known, and so on; and the author has amply satisfied their wants in this direction. Indeed, the whole book bears evidence that its writer has had considerable experience in the teaching of elementary students.

Electricity in Our Homes and Workshops. Third Edition. By S. F. Walker. (London: Whittaker and Co. 1895.)

In this short treatise the author has sought "to explain in simple terms the ordinary everyday working of some forms of electrical apparatus that are in use by outsiders, and not under the constant supervision of trained electrical engineers." Commencing with a glossary, in which a number of popularly expressed explanations of electrical terms have been collected together, the author passes on to consider, in successive order, the properties of the electric circuit, the simplest phenomena of magnetism, and galvanic batteries. Thus is the first half of the book arranged; the remaining half being devoted to the elements of practice connected with electric bells, electric mining signals, and telephonic apparatus. The descriptions are free from difficult technical details, and are such as might readily be comprehended by non-technical readers. And to this class of readers this little book may be recommended. The work is copiously and, in general, usefully illustrated.

GAS ENGINE ELECTRIC SUPPLY STATIONS.—III.*

Morecambe.

The first gas-engine station for the generation of electric energy for public supply in the United Kingdom was that which was erected at Morecambe, in Lancashire, in 1892. And this station possesses a further interest, from the fact that it was almost from the first driven by engines supplied with Dowson producer gas. Only for a short time at the start, was town gas used in this station; and we understand that the Dowson producers have been continuously used from the time of their introduction.

The station itself was somewhat of a tentative and temporary venture, it having been intended to make the experiment with the rather inadequate accommodation afforded by these quarters, and subsequently to transfer the generating plant to a more substantial and more conveniently situated house. The necessity for this removal to other quarters has, unfortunately, been emphasised by the fact that complaints have been made by the occupants of houses around the present station, that the waste gases from the generators and engines have created a nuisance. The transfer of the plant to a stone building not in a residential district is being contemplated; and the change would probably be found to be advantageous.

* All rights of reproduction are reserved. Articles I. and II. appeared on June 28th and July 26th respectively.

Digitized by Google

At the present time the equipment of the station comprises the following details:—There are three Dowson gas generators, two of 75 H.P. and one of 150 H.P. capacity. These are connected to a gas tank, having a maximum capacity of 1,500 cubic ft. Steam for the gas generators is raised in one or the other of two small vertical boilers. The engine plant comprises one Crossley gas engine, of about 100 H.P., and three "Stockport" gas engines, each of 25 H.P. The dynamo plant includes two small two-pole continuous-current generators, one large machine of similar pattern, and one six-pole machine, which is partially used as an alternator and partially as a continuous-current generator. Each of these machines is belt-coupled to a separate gas engine, the 100 H.P. engine driving the six-pole machine. There is a small storage battery, comprising 72 E.P.S. cells of the K type.

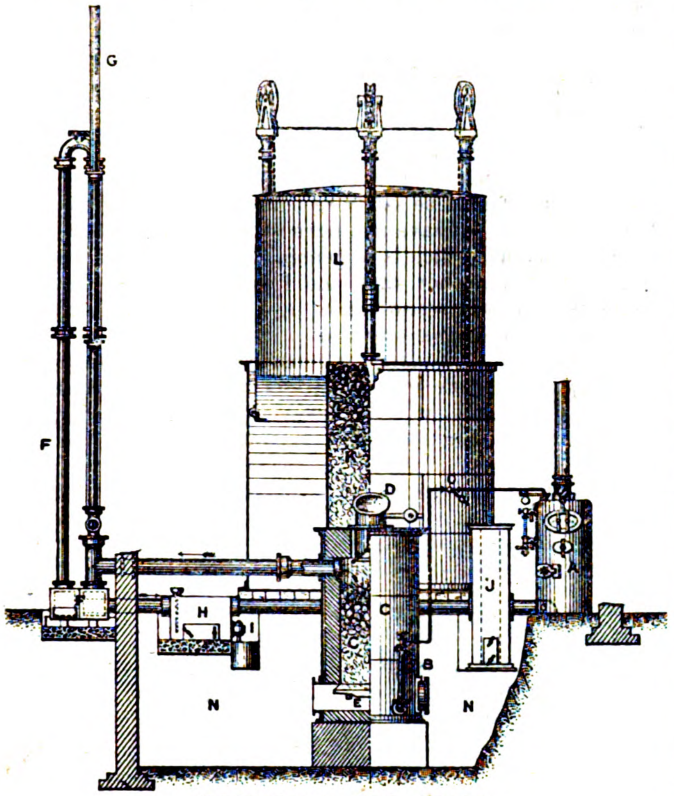

FIG. 1.—Dowson Gas Generating Plant.

As the chief interest in this station arises from its gas-engine equipment, we will devote our chief attention to the details of this, reserving for the conclusion a few remarks upon some of the electrical features.

Fig. 1 shews an elevation and vertical section of one of the units of Dowson gas generating plant, together with the gas tank and connecting pipes, &c. The generator or producer itself is shown at C, and it consists of a brick-lined furnace, wherein anthracite, supplied through the door D, is fed with a blast of admixed steam and air. The steam is generated in the boiler A, and is usually superheated on its passage from the boiler to the steam range or pipe O. Through the imperfect combustion of the incandescent carbon or anthracite, and the dissociation of the steam, a diluted fuel, known as Dowson water-gas, is generated in the furnace C. These admixed fuel gases, comprising hydrogen, carbon monoxide, carbon dioxide and nitrogen, in very varying proportions, according to the conditions of generation at the moment, are passed from C through the gas pipe to the coolers F. These coolers consist of a stack of vertical cast-iron pipes, giving sufficient radiating surface to reduce the temperature of the gas to ordinary limits. From the coolers the gas passes through the hydraulic box or water trap to the sawdust scrubber J, and thence to the coke scrubber, which in Fig. 1 is shown to be inside of the gas-holder, at K. Passing up through the coke scrubber the gas will collect in the small gas tank or holder L, from which it is drawn off as required for use in the engines. More commonly, and in the actual plant at Morecambe, the coke scrubber is separate from the gasholder. A view of the Morecambe gas-house is shown in Fig. 2.

The steam in the boiler is generated at a normal pressure of 60lb. per square inch; and it is not found to be economical to reduce this pressure very considerably on light loads. The quality of the gas very much depends on the boiler pressure, or rather, on the pressure of the steam blast. Too great a reduction of pressure generates poor gas. Normally, about 120lb. of coke per hour is burned in the working boiler.

The sawdust scrubber is re-charged every three weeks, and the coke scrubber once only every six months. We have found

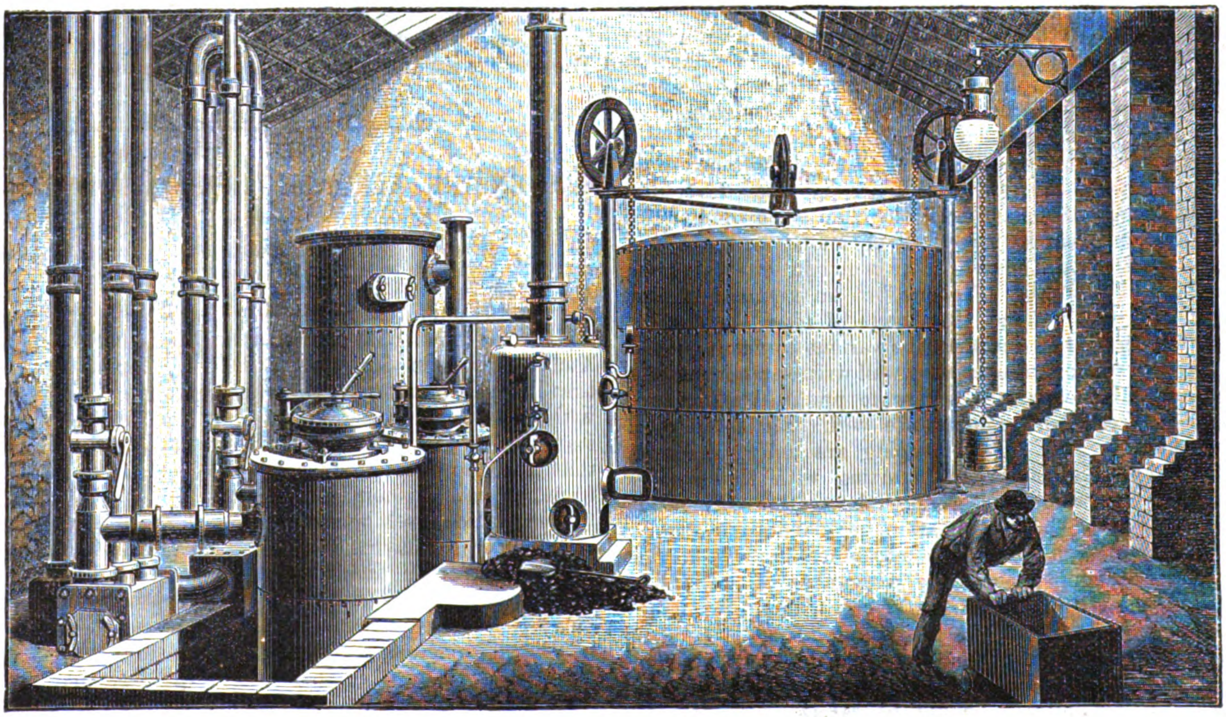

FIG. 2.—Morecambe Electric Supply Station. Gas Generator House.

in other places that a more frequent change in the charges, especially of the sawdust, is advantageous.

The gasholder is of 1,500 cubic ft. capacity; it is thus only large enough to serve as an equaliser of the pressure, for full load on the station will empty it in ten minutes if a gas producer is not working. We should like to see the experiment of a much larger holder for Dowson gas tried, as under those conditions the gas could be generated more regularly and in better quality. As it is, the changes in the load on the engines are also thrown upon the gas producers, which are intrinsically ill-fitted to stand severe changes of load.

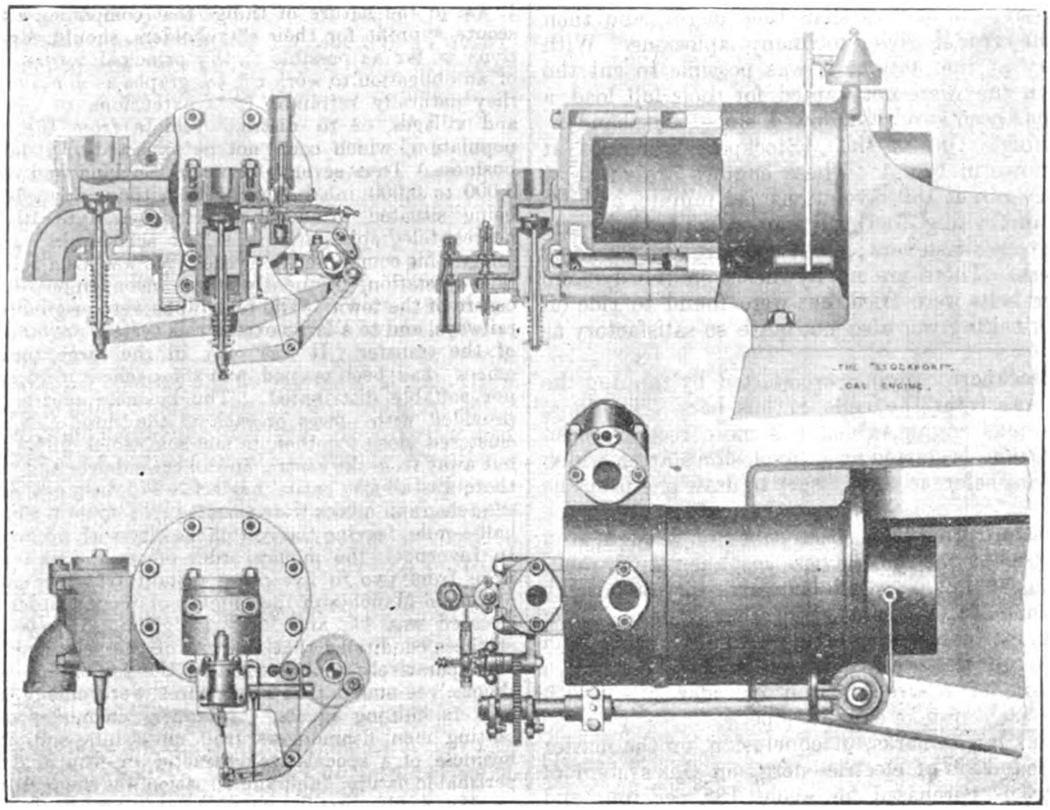

Fig. 3.—Valves and Valve Gear of the "Stockport" Gas Engine.

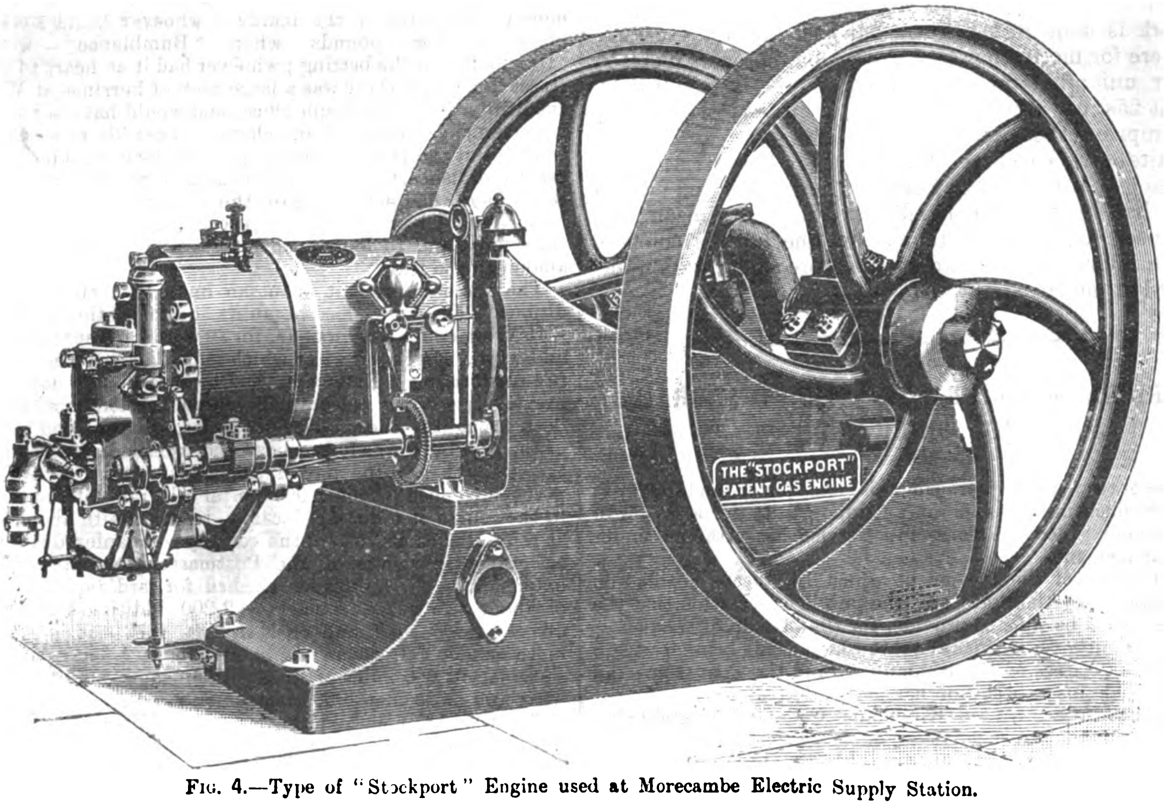

Fig. 4.—Type of "Stockport" Engine used at Morecambe Electric Supply Station.

Fig. 3 shows the usual arrangement of the "Stockport" gas-engine valves, valve gear, &c.; but it is interesting to note that this has been considerably modified in the Morecambe plant. Neither the governor shown in the illustration nor the graded-charge governor is used; for, on these engines all governing has been abandoned, except to prevent the engines from excessive racing, and the engines are left to develop full

load during all the time they are running. It had been found that with close miss fire governing there was not sufficient steadiness in the light, owing to the vice which the engines developed of missing more fires than they ought, and then making up for the error by giving too many explosions. With a storage battery at the station, it was possible to cut the engines out when they were not wanted for their full load, a practice which has been steadily followed since the abandonment of governing. One of the "Stockport" engines at Morecambe is shown in Fig. 4. These engines are rated at 25 H.P. each, they run at 180 revolutions per minute, and are coupled by cotton belting to the dynamos. The belts are fastened by Lagrelle's fasteners; and they have run for three years with success. There are no flywheels on the dynamo shafts. Leather belts were tried, but were found to ride off the pulleys; link belting was also not quite so satisfactory as the cotton kind.

The three "Stockport" engines are started by running the dynamos as motors from the cells or 'bus bars. The large 100 H.P. Crossley gas engine, which has more recently been erected in the station, is started by an explosion starter, which gives six explosions before it is necessary to draw gas from the mains.

All the engines are fired by ignition tubes of wrought-iron steam pipe, plugged at one end. These cost about 1·5d. each, and last for about 50 hours; which compares very favourably with the magnitude of this item at some other stations. Each engine has a separate exhaust up-take, passing vertically from the engine through the well-ventilated roof. There is a silencer, consisting of a wrought-iron cylinder filled with shingle, capping each up-take exhaust pipe.

We may make a few remarks, in conclusion, on the matter of the cost of production of electric energy on this system of generation. Coal is purchased for about 18s. per ton, and at that rate the average cost of fuel per unit metered out of the station, during three months of working, was about 0·5d. per unit. On short runs Mr. Collinson has succeeded in bringing the cost down to 0·3d. per unit. The normal load on the station, in lamps wired, is 3,000 lamps, including the equivalent of some 40 small arc lamps. A small trade in motor work is done in the town, but there is not excessive demand here for motive power. Power for motors is metered at 7d. per unit; but for all lighting, power is supplied by contract at 25s. per annum per 16 c.p. lamp, and the equivalent for lamps of other power.

The entire work has been carried out by Messrs. Andrews and Preece; and the management of the station and system of supply has been in the hands of Mr. P. Collinson, the chief engineer, to whom our thanks are due for the courtesy with which information regarding the Morecambe station has been placed at our disposal.

HISTORICAL OUTLINE OF THE TELEGRAPH SERVICE SINCE 1870.*

The lapse of twenty-five years since the transfer of the telegraphs to the Post Office in 1870, affords an opportunity for a review of the development which the Telegraph Service has attained under national management.

The mainspring of the movement which led to the acquisition of the telegraphs by the State, was the public expectation that the Post Office would be able to provide, for the benefit of the nation as a whole, an improved service at a rate which would bring it within the reach of all classes of the community, and the Post Office can justly claim that this expectation has been fulfilled.

The attempt of the "United Kingdom" Company to establish a uniform rate of 1s., irrespective of distance, had failed, and in 1869 the tariff charged by that Company, as well as by its older rivals, the Electric and International, and the British and Irish Magnetic, stood at 1s. for a message of 20 words for distances up to 100 miles, 1s. 6d. up to 200 miles, and 2s. beyond 200 miles in Great Britain. For messages between Great Britain and Ireland the charges ranged from 3s. to 6s. In many instances these rates, high as they were, did not cover the whole transmission of a telegram. They only applied to the wires of a single company, and where a message had to be transmitted over the systems of two or more companies, an additional charge, frequently of considerable amount, was levied.† Not only were the charges high, but the systems were incomplete. It was in the nature of things that companies whose aim was to secure a profit for their shareholders, should restrict their operations as far as possible to the principal towns. In the absence of an obligation to work the telegraphs as a national undertaking, they naturally refrained from extensions to the smaller towns and villages, or to districts remote from the chief centres of population, which could not be expected to yield a remunerative business. Thus several towns in England and Wales with from 3,000 to 6,000 inhabitants were without any telegraph facilities, being situated at distances of from 5 to 10 miles from the nearest telegraph station. Where such towns were provided with telegraphic communication, the office was, as a rule, situated at the railway station, frequently at an inconvenient distance from the centre of the town. The telegraphs were originally confined to the railways, and to a large extent this system prevailed up to the time of the transfer. It was only in the large towns that "town offices" had been opened, and these offices were neither numerous nor suitably distributed. The business centre of the town was provided with offices of each of the three competing companies clustered close together, in fact sometimes only a few yards apart; but away from the centre, and in the suburbs and outlying districts, there was almost entire neglect. For instance, in Edinburgh all the telegraph offices were situated in a circle with a radius of about half-a-mile, leaving the rest of the city with no provision whatever. In Liverpool, the money order offices for six suburban districts were from two to five miles distant from the nearest telegraph office; in Manchester the number of money order offices similarly situated was 11, and in Birmingham. It was a natural result of these conditions that the use of the telegraph was confined to a comparatively small section of the population. The companies themselves stated that their wires were chiefly used by "stock-brokers, mining agents, shipbrokers, colonial brokers, racing and betting men, fishmongers, fruit merchants, and others engaged in business of a speculative character, or who deal in articles of a perishable nature," and the situation was thus graphically described by Mr. Scudamore in one of his reports: "By maintaining high charges as long as they could; by reducing those charges inch by inch, as it were, and only under pressure; by the confinement of their operations to important towns, and by planting their offices mainly in the business centres of those towns, the telegraph companies had brought speculative men, and speculative men only, to a free use of the telegraph. Whoever could make money on a turn of the market; whoever could advantageously place a few pounds when 'Bumblebee' went below 'Dulcibella' in the betting; whoever had it at heart to let Thames-street know that there was a large take of herrings at Wick, rushed cheerfully to the telegraph office, and would have submitted to any inconvenience, and paid any charge, to get his message through in time. But the general public, puzzled by a variable and complex tariff and disheartened by the distance of the telegraph offices from their doors, had got to regard the telegraph as a medium of communication which they might use in times of sore necessity, and then only, and to look upon a telegraph message with a feeling amounting to fear."

The transfer brought about an immediate change in these conditions. The Post Office began its administration of the telegraphs with the moderate tariff of 1s. for 20 words, irrespective of distance, and with a system of wires which it had already been instrumental in transforming. Extensions had been made to a number of places previously without telegraphic communication, and the wires had been brought to the suburbs of the larger towns and to the centres of the smaller towns formerly served from the railway stations, with the result that on the day of the transfer the Post Office was in a position to open about 1,000 postal telegraph offices, situated each in the centre of a distinct locality, together with about 1,900 offices at railway stations, where the railway companies dealt with public telegrams as agents of the Postmaster-General. The work of extension on these lines was pushed forward rapidly. In a period of about two years, as many as 2,200 additional postal telegraph offices were opened, and on March 31, 1872, the system comprised more than 5,000 offices (including about 1,900 offices at railway stations), 22,000 miles of line, with an aggregate of 83,000 miles of wire, and more than 6,000 instruments.

The year 1872 marked the first stage in the development of the postal telegraphs. In that year, the third of the administration by the nation, the extensions undertaken with the view of providing a fully-equipped telegraph system had practically been completed, and the result was seen in a large expansion of business. In the first year after the transfer, the number of telegrams of all

* From the Postmaster-General's Annual Report.

† Besides the companies here mentioned, there were the London and Provincial, the Universal Private, and a few other small companies. There was nominally a "local" rate of 6d. in London and some other large towns, but its scope was so restricted that it only applied to about 2 per cent. of the total number of telegrams.

Digitized by Google

descriptions was about 10,000,000, in the second about 12,000,000, and in the third (the financial year ended March 31, 1873) over 15,000,000, or more than double the number in 1869, which was less than 7,000,000. The period from 1872 up to the adoption of the sixpenny tariff in 1885 was one of steady progress. The addition of new offices was not large, the total of 5,000 offices in 1872 having only increased to 6,000 in 1885. But great improvements were made in the means of communication between places already connected, and the increasing appreciation of the telegraph service by the public was shown in the fact that in 1885 the number of telegrams had again been more than doubled, having risen to 33,000,000.

The reduction of the tariff in 1885 opened a new era. A comparison of the old tariff of 1s. for 20 words with 3d. for each additional group of five words, and the new tariff of 6d. for 12 words with ½d. for each additional word is complicated by the fact that the free addresses allowed under the former tariff were abolished under the latter. But the point that can be clearly seen is that, whereas it had been impossible to send a telegram, however short, at a less charge than 1s., a telegram of 12 words could now be sent for 6d. The fact that addresses were now charged for, did not prevent the senders of telegrams from so reducing the number of chargeable words as to obtain the full benefit of the lower tariff. The actual length of the telegrams was largely curtailed, especially in the addresses; and economy was effected through the operation of certain new rules, one of which prescribed that figures, formerly chargeable each as a single word, should be counted at the rate of five figures to a word. In the result a large proportion of the total number of telegrams was brought within the minimum charge of 6d., while the average charge, which had been 1s. 1d. in 1885, was reduced to about 8d. in 1886, and has since fallen below 7¾d. Under the reduced tariff, telegraph business again received a powerful stimulus. The charge was so low as to popularise the telegraph service still further, and to render it available for purposes for which it had not hitherto been used. In particular, it became adapted to the requirements of local traffic; and in London the local telegrams were more than doubled in about two years, having risen from about 1,800,000 in 1884-85 to 3,800,000 in 1886-87.

The Post Office has had to contend with an increasing competition on the part of the telephone companies, who have chiefly competed in that class of business, the local traffic, which afforded, under the new tariff, the greatest promise of growth. It is stated by the National Telephone Company that the volume of their business is equivalent to 280,000,000 messages of an average length of 100 words. A certain proportion of this vast business would undoubtedly, in the absence of the telephone, have been transacted by telegraph; but, notwithstanding the loss to the telegraph service in this respect, a development exceeding that between 1870 and 1885 has actually occurred. The number of telegrams of all descriptions, which had reached 33,000,000 in 1884-85, rose to 50,000,000 in 1886-87 and 62,000,000 in 1889-90, while in the financial year just expired a total of 71,589,000 has been attained. With the possible exception of the United States, for which complete statistics are not available, no other country in the world makes so extensive a use of the telegraph. In France the number of public telegrams is about 42,000,000, in Germany 33,000,000, in Austria and Hungary 18,000,000, in Russia 13,000,000, and in Italy 10,000,000. In the United Kingdom about 184 telegrams are sent for every 100 persons, as compared with 108 for the same number of persons in France, 66 in Germany, 42 in Austria-Hungary, 31 in Italy, and 10 in Russia. The nearest approach to the United Kingdom in this view is Switzerland, where the number of telegrams per 100 persons is about 127; even Belgium does not produce more than 87 per 100 persons. An adequate idea of the volume of telegraph business in the United Kingdom cannot, however, be gathered from these figures alone. The tariff for Press telegrams in this country, working out, as it does, on the average, at about 4½d. per 100 words, is the lowest in the world, and the amount of work performed for the Press is without a parallel in any other country. Although the Press telegrams, 5,400,000 in number, are included in the total of 71,589,000, no allowance is made for their exceptional length. Being of an average length of about 120 words, they contain an aggregate of about 650,000,000 words, as compared with an aggregate of about 970,000,000 in all other telegrams. Under the arrangements for news telegraphy this number of words does not, it is true, entail on the Post Office a corresponding amount of work; but it is a striking fact that the words dealt with for the Press form no less than two-fifths of the total number of words.

The growth of the whole business since 1870 (from less than seven to more than seventy-one millions) has been more than ten-fold. The number of offices has increased from 3,000 to nearly 10,000. The system, including submarine cables, now consists of about 35,000 miles of line, as compared with 15,000 in 1870, and about 215,000 miles of wire as compared with 60,000, while the number of instruments has increased from about 4,000 to over 26,000.

But for the improvements which have been effected in telegraphy since 1870, the increase in the mileage of wire and the number of instruments must necessarily have been much greater. It was urged at the time of the transfer that the possession, by the Government, of a monopoly in telegraphs would tend to discourage invention. To this contention the progress achieved in the technical department of the telegraph service is a sufficient answer. Partly through the adoption of outside inventions (with due recognition of the rights of the inventors) and partly through improvements devised by its own staff, the Post Office has succeeded in largely increasing the working capacity of the wires. The improvements are too numerous to be set forth in detail, but it may be well to mention some of the more striking. In 1870, each wire only afforded a single channel for communication. At the present time a single wire can be used for the simultaneous transmission of two messages under the duplex system (which may be said to be the normal method of working between busy offices), four under the quadruplex system, and six under the multiplex system. These inventions were obtained by the Post Office from outside (the duplex from Mr. Stearns, the quadruplex from Mr. Edison, and the multiplex from Mr. Delany), but their value for practical purposes is largely due to the efforts of the officers of the Post Office to develop and improve them. No less important than this increase in the number of available channels of communication is the improvement in the speed of working. In 1870 a speed of from 60 to 80 words per minute was the highest which could be attained in the working of the Wheatstone automatic apparatus. At the present time a speed of 600 words per minute has become possible, and a working speed of 400 words is the fixed standard for certain circuits. The duplex system has been successfully applied to the automatic apparatus, with the result that many circuits are working at a speed of 250 words per minute in two directions. Two copper wires between London and Dublin are working on the duplex system at even 300 words per minute, whereas under the conditions of 1870 they would only have given about 40 words in one direction as a maximum. The "repeaters" used for strengthening the current on long circuits have also been greatly improved. In the absence of repeaters it would be impossible to obtain a higher speed than 40 words per minute between London and Aberdeen, whereas with repeaters at Leeds and Edinburgh a speed of 350 words is attained.

The financial side of the telegraphs unfortunately does not present so favourable an aspect. It is undoubtedly a matter for concern that during the year ended March 31st last the expenditure exceeded the revenue by about £154,000, to which must be added the interest (£298,000) on the capital expenditure incurred at the transfer, making the total loss for the year about £452,000. In the period of 25 years since 1870 the receipts show a balance of about £1,795,000 in excess of the expenditure, but they fall far short of meeting the interest on capital, the aggregate deficiency in this respect being £5,859,000. The large price paid as purchase-money on the terms authorised by Parliament is one of the factors which have contributed to the unfavourable financial results of the working of the telegraphs. The expenditure on capital account amounted to about £10,130,000. Of this amount about £2,130,000 was expended on extensions, and the remainder, £8,000,000, in the purchase of the undertakings of the telegraph companies and the interest of the railway companies in public telegraphs. It is generally held that the companies were liberally treated, and in certain cases a price which must be regarded as excessive had to be paid. The right, accorded to the railway companies at the time of the transfer, of sending postal telegrams free of charge, has proved another burden. The number of the railway free telegrams, at first insignificant, increased out of all proportion to the growth in ordinary public telegrams, until in 1891 it reached a total of about 1,600,000 telegrams, representing, at 1s. 0½d. per telegram (the average length being 25 words), a value of over £80,000 per annum. It is, however, a matter for satisfaction that arrangements have recently been made under which this burden is materially lessened, while a barrier is imposed against future growth. A still more serious burden is caused by the loss on Press telegrams. The charge specified in the Telegraph Act of 1868 for Press telegrams is 1s. for 75 words during the day, or for 100 words at night. But a proviso was added that for copies the charge was to be only 2d. per 75 or 100 words, and no condition was laid down as to the copy being for the same town as the original. The newspapers accordingly combined to receive, from the news associations, messages in identical terms, and by dividing the cost they are enabled to get the benefit of a rate which comes nearer 2d. than 1s., the average charge being, in fact, about 4½d. per 100 words. Notwithstanding the economical arrangements which have been made for the transmission of the telegrams (5,400,000 in number, containing 650,000,000 words), the loss incurred by the Post Office in dealing with them is estimated to amount to £300,000 per annum.

These unfavourable conditions have permanently affected the telegraphs. They must in any case have diminished the possibility

Digitized by Google

of profit, and in the actual circumstances their effect has been to augment the loss. Moreover, new influences inimical (temporarily if not permanently) to financial success have come into play, namely, the reduction of the tariff in 1885, the increase in the pay of the staff, and the competition of the telephone companies for local traffic.

The results of the alteration of the tariff in 1885 have been described in an earlier paragraph. While the average amount received for a telegram was reduced from 1s. 1d. to 7¾d., a large addition was made to the main element of cost, namely, the pay of the staff. The proportion of the amount expended on salaries and wages to the total telegraph expenditure, which in 1881, before the revision carried out by Mr. Fawcett, stood at about 55 per cent., has since risen, as the result of that revision and the revision effected by Mr. Raikes in 1890, to about 65 per cent. At the same time the competition of the telephone companies deprived the Post Office of a large portion of what was at once the most promising and the most remunerative part of its business. There has, it is true, been a development of local telegraph traffic since 1885, but in recent years the increase has been materially checked. In certain cases the traffic conducted by the Post Office in the large towns, or between large towns situated at a short distance from each other and connected by the trunk wires of the National Telephone Company (as, for example, between Glasgow and Greenock, and between Liverpool and Manchester), has suffered an actual diminution.

Against the loss of money incurred on the telegraphs must be set the benefits which the system confers on the community. That an expeditious service, extending into every part of the United Kingdom, is provided at a charge of less than 8d. per telegram, is an advantage for the whole nation which may be regarded as at least commensurate with the sacrifice entailed by the financial loss. The amount provided by the taxpayers to meet the deficit is not lost; it is virtually repaid in services for which a higher charge would otherwise have had to be levied, and the main object of the acquisition of the telegraphs by the State may be said to have been realised in the attainment of a development to which no other country affords a parallel. The Post Office has to admit a deficit on the working of the telegraphs, but its 71,000,000 telegrams bear testimony to the value of the service which it renders to the public.

THE STRUGGLE BETWEEN TELEGRAPH AND TELEPHONE.*

BY PATRICK B. DELANY.

I have been much interested in the attention you have been giving to the telegraph and telephone situation of late, and although in general touch with both subjects, I was startled by your graphic presentation of the power and proportions gained by the telephone during the few years of its existence. It is easy to understand that if the telegraph and telephone continue their growth in the future in the same ratio as in the past, it will not be long before the telephone is greater than the telegraph in property and earning capacity. Indeed, judging from the great disproportion in the development of the two systems, and the constantly increasing gains of the telephone relatively, the decline of the telegraph, if conducted on the present plans, may be reasonably expected. There is no escape from the self-evident fact that the telephone has been managed with energy and enterprise, while the telegraph has been guardedly confined to the old conservative grooves, blind to the march of events, and deaf to the demands of development. Before the telephone was born the telegraph might have, to a large extent, occupied its field and earned a large revenue from telegraphic *conversations*. The demand for such facilities was *forced* upon the notice of the telegraph companies constantly, but the idea was frowned down, and only in rare cases, and as a great favour, were privileges of this kind granted. It is my firm belief that even at this late day type-written conferences by telegraph would be popular and profitable if the telegraph companies would take the trouble to bring people to the ends of the wire as the telephone companies are doing.

Viewing the whole subject of communication and correspondence broadly, one cannot fail to be impressed with the fact that after all the telegraph and telephone combined do but a small proportion of the work. There are about three billion sealed letters carried by the Post Office during the year, or about 40 letters to one telegram, and this difference in number is owing mainly to the difference in cost.

It might as well be admitted at once that the telephone holds the field for local communication, mainly because of the subscriber system, the lump-sum yearly charge, regardless of the number of messages, and its ever-ready facilities. The local telegraph, as everyone knows, is slower than the long-distance lines. It takes less time on an average to send a telegram from New York to Chicago than from Madison-square to Wall-street. Nor is the telephone service to occasional or outside users much better in this respect, as everybody that has wrestled with a local pay station outfit, its "Hello's," "Number's," "Busy now's," &c., &c., can testify. With subscribers it is different. The facilities are so much more convenient and the service so much quicker, that in these days no telephone subscriber would think of sending a telegram to his correspondent in the same town.

Leaving local communication to the mails and the telephone, the more important question of communication between distant points is the one to be dealt with, and it is to this domain that the struggle for supremacy between the telegraph and the telephone will be confined. I cannot believe that telephony at nine dollars for five minutes' use between New York and Chicago and proportionate charges all over the country will ever become popular to any great degree, even though it should yield the 150 words per minute with which you credit it, a speed, however, which I think is more than double its capacity in the hands of the average user. There are but few public speakers that will average 150 words per minute in delivering an address. That such a rate can be wrung out of a telephone with all the interruptions, repetitions, and miscellaneous skirmishing in getting down to work, seems highly improbable. It seems to me that a word a second, 60 words per minute, or 300 clearly understandable words in five minutes, would be a very liberal rate for telephony, and this without any record, unless one employs a stenographer to take it down, thereby adding to the trouble and expense, and introducing another fertile element of doubt and distraction. When it is remembered that this rate of 60 words per minute involves the use of *two* wires, the capacity of the telephone for correspondence is not as great as that of the telegraph, even with its present slow method of hand working; for a quadruplex will carry 60 words per minute over one wire. Reckoning the eight operators engaged in the telegraph work as a partial offset against the second wire of the telephone, matters will still be in favour of the telegraph with the additional advantage that in the case of the telegraph the 60 words per minute may be type-written, whereas the telephone message is in the user's head, not always a reliable reference. The cost of 300 words type-written by telegraph at regular rates would be $9.10, or 10 cents more than the telephone charge, assuming 300 words to be a fair clean-up product of five minutes' conversation.

Thus it would seem that as at present organised for work the telegraph and the telephone are about on a level. But the telephone has insuperable advantages in its subscriber system and the facilities afforded for *completing* a conference or transaction on the spot. So long as a business man in New York can, without leaving his office chair, confer with another business man a thousand miles away, and get his reply on the moment, he will pay the price *whenever the occasion warrants*, but he will not write telegrams, send them to the telegraph office and wait from one to four hours for the answer, *at the same cost*.

It is plain, however, that at the present rates the telegraph and telephone combined cannot get more than 4 or 5 per cent. of the number of messages carried by the Post Office. They will continue to be used in cases of urgent necessity represented by this percentage and no more.

In the battle for supremacy, the telegraph is infinitely more resourceful than the telephone. With the present system of operation, but 5 per cent. of the carrying capacity of the present telegraph wires is utilised, and with larger copper wires speeds may be enormously increased. Not so with the telephone; the speed of which must, under most favourable conditions, be limited to the rate of human articulation. When telegraphy is broadened to its proper function, the mails will be carried by it over all important routes, and the railway time for a letter from New York to Chicago will be practically eliminated, or reduced from about 25 hours to the telegraph speed of a few seconds—and with a rate of 15 cents for 50 words, or 90 cents for 300 type-written words against nine dollars for the same message over the telephone, using two wires, the degree of urgency requiring the use of the telephone would be of great rarity, while at the same time, the incentive to save so much time over the regular mails would result in an enormous traffic for the letter telegraph. No telegraph engineer will now deny that it is practicable to send 1,000 words per minute over an 850 pound per mile copper wire from New York to Chicago, producing a record from which type-written translation can be made at the rate of 50 words per minute, or that 1,000 words can be prepared for transmission as quickly and as cheaply as it can be telegraphed by hand. Therefore it would be difficult to avoid the conclusion that automatic or machine telegraphy, with chemical recording, will carry the bulk of the correspondence too urgent for the regular railway transportation and not urgent enough for the telephone and its great expense. Letter telegraphy is only a question of copper, construction, and chemical automatic working. The telegraph with a differentiated

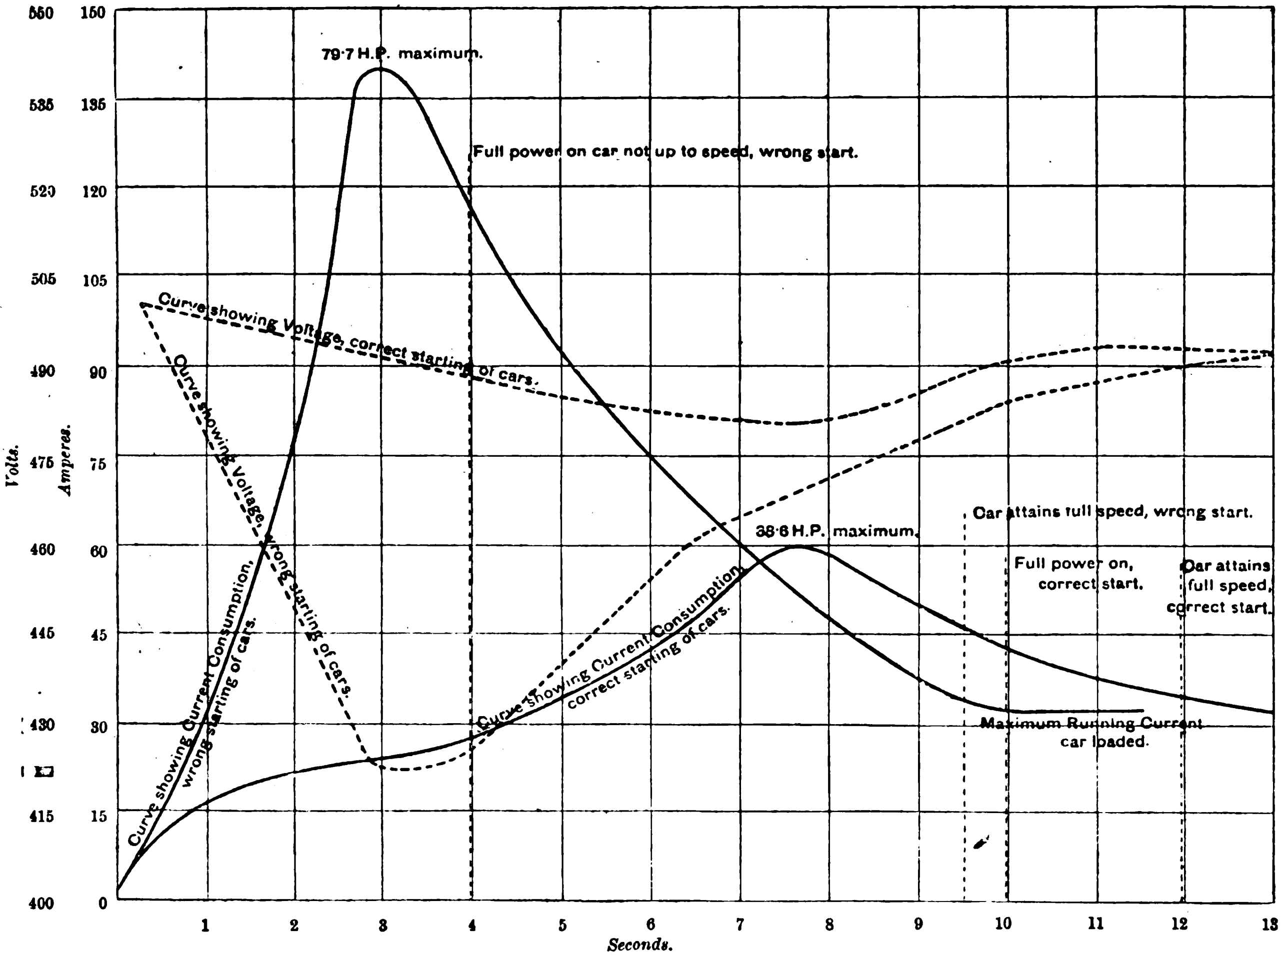
service, amplified to meet the various grades of exigency, and with rates made possible by machinery which will bring into use the 95 per cent. of efficiency now wasted, should stand in no great dread of the telephone.

HOW TO START A CAR.*

The abuse of motors by too rapid handling of the controller has been harped on ever since electric roads were first started, and every competent superintendent realises the importance of educating motormen not to turn on current too fast. At the same time acceleration with the motors in series. The somewhat startling results shown by the upper curve in the diagram are caused mainly by throwing in multiple too quick.

One of the most interesting and encouraging things about the diagram is the small gain in time which is made by the wrong start. There has been a constant tendency of late years toward quick starts in order to make a fast schedule. A heavy starting current has been considered as something which could not be avoided in this connection. Mr. Knox's investigations show, however, that if the controller is handled rightly there is very little time lost by the correct as compared with the incorrect start, while there is an enormous saving in current and consequent strain on the motors.

The facts brought out by the tests have, of course, been known in a general way by electrical engineers for some time, but they



Curve Plottings of actual tests made on the road, showing power consumption of motor cars in correct and wrong starting. Plottings show an average of a series of tests.

	Wrong starting of cars.		Correct starting of cars.
Time in which full power is turned on	4 seconds	....	10 seconds
„ „ „ speed is attained	9·5 seconds	....	12 seconds
Distance car has travelled when full power is on	13·5 feet	....	110 feet
„ „ „ „ speed is attained	85 feet	....	150 feet

	Wrong starting of cars.		Correct starting of cars.
Maximum current consumption in making start	140 amperes	....	60 amperes
Volts drop in making start	80 volts	....	20 volts
Watt-seconds consumed in making start	307178·4	....	221676·0
Average H.P. used in starting	43·3	....	24 7
Average loss in H.P used in. starting per car	15·6	....	

nearly every superintendent laments the difficulty of getting men to observe at all times the rules about slow starting.

It is seldom that the difference between a correct and a too quick start is illustrated as graphically and unmistakably as in the accompanying diagram, which represents the results of a series of tests made on the Chicago City Railway by Mr. G. W. Knox. Blue prints of this diagram are posted at all the car barns for the benefit of motormen. By insisting on the observance of the lesson which this diagram teaches, and by suspending for a few days those who refuse to learn, the current output per car at the power station has been reduced by a large percent. This, of course, also means a saving in repairs.

A series-parallel controller requires a very different handling from the old style of rheostat, and in some cases motormen and those who educate them do not seem to recognise the peculiarity of this method of control. While the initial starting current is not very high with this kind of controller there is a sudden rise when the change is made from series to multiple, and particular care needs to be taken not to throw in multiple until the car has attained its full

are not often put in such definite shape as here, and consequently they are not as fully realised and acted upon by all concerned as they ought to be.

THE OVERHEAD WORK IN THE BELT LINE TUNNEL, BALTIMORE.

The following particulars with regard to the overhead work and form of trolley adopted for the purpose of electric traction in the belt line tunnel at Baltimore, which have appeared in the American papers, will be read with interest. It should be pointed out that in this case electric traction had to be adapted to the traffic instead of the traffic being adapted to electric traction. The tunnel is only a link in a through line, and long trains of the ordinary kind have to be hauled through, locomotives and all, just as they are. The locomotives weigh some 96 tons, and take currents of from 500 to 3,000 amperes.

Digitized by Google

The conductor selected is a trough formed by two 3in. Z-shaped iron bars in which slides a shuttle-shaped brass trolley shoe. These Z-shaped bars (*see* Fig. 1) are ⅜in. thick riveted to a cover plate ¼in. thick and 11½in. wide. The feeder wires are attached by cleats to the transverse frame supporting the "up" and "down" conductor troughs and midway between them. The trough is made in 30ft. sections, weighing 90lb. to the yard. Outside the tunnel the method of suspension consists of lattice steel poles on either side

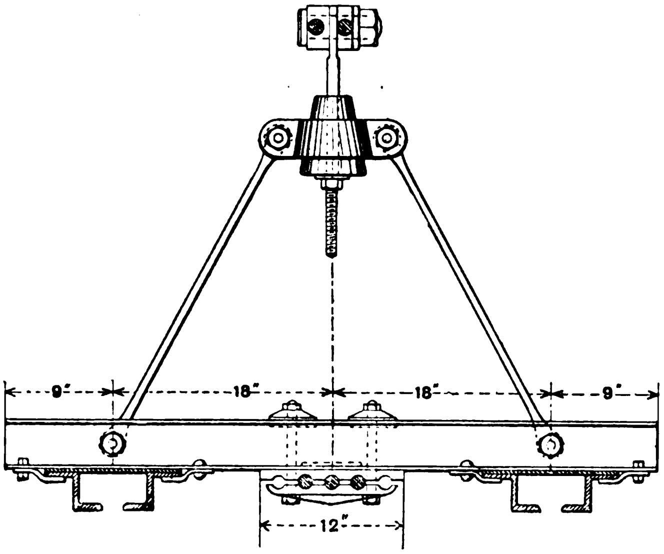

FIG. 1.—Section through Overhead Work.

of the track, carrying between them transverse trusses. From these trusses, which are 50 yards apart, are stretched chains of iron rods, from which vertical rods are dropped down at intervals of 15ft. to support the current-carrying trough. In the tunnel the conductor is supported every 15ft. from transverse frames hung from the arch. Inside the tunnel the conductor is 17½ft. above the track, outside it is 22ft. In Fig. 2 is shown the form of trolley adopted.

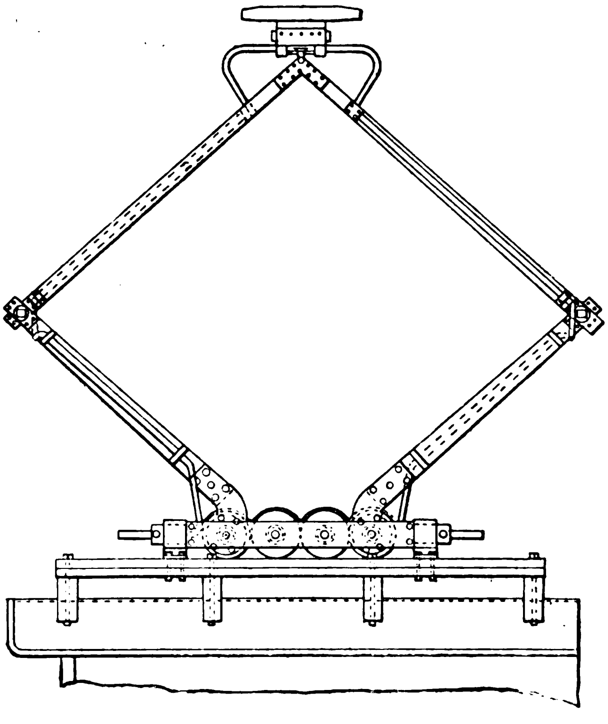

FIG. 2.—Trolley.

During the trial trips some difficulty was experienced from the fact that in the tunnel the moisture had acted to form a coating of high resistance inside the trough, consequently when a heavy current was taken off the trolley shoe became red hot and almost welded itself to the trough. This impromptu welding trouble has, however, now been overcome by a thorough cleaning out of the trough, which will in future be kept clear by the constant traffic through the tunnel.

THE HERMITE PROCESS OF DEODORISING SEWAGE.*

BY J. NAPIER, F.C.S., F.I.C.

The treatment of sewage for the purpose of preventing putrefaction is a subject which has occupied the minds of chemical and sanitary engineers for many years, and numerous methods of dealing with it have been devised and brought before this and other societies, each claiming to perform its work in a more perfect manner than its predecessor. Those methods, with only one or two exceptions, treat the sewage at a point between the last inlet into the main sewer and the outfall, usually at the outfall, and as far away from the town as it is possible to put it. Those systems of dealing with sewage at the outfall do not give the town from whence it came any sanitary benefit. They do not prevent sewer gas accumulating in the sewers and escaping into the air from manholes or ventilating shafts and becoming an annoyance and nuisance to the inhabitants. The objects of those systems of treating sewage, then, is to purify the sewage sufficiently to prevent the pollution of a waterway or river, and without in any way being of the slightest benefit to the health of the town.

With the Hermite process the sewage is treated at the other end of the sewers—*i.e.*, at the beginning—deodorised there, so that flowing through a town the sewers give off no offensive smells, and the putrefactive changes which take place in sewage have been arrested. With this system, then, there is no need for ventilating shafts, and if the manholes are perforated there is no offensive smell given off; on the contrary, there is a faint chlorous or bleach smell, which is much more acceptable to the nose than sewer gas. The principle of this process is passing a current of electricity through sea-water, or, if sea-water is not handy, a solution of magnesium and sodium chlorides; a portion of these chlorides is converted into hypochlorite, a substance which disinfects, deodorises, and bleaches, and is similar to the active ingredient of bleaching powder—calcium hypochlorite. The change from chloride to hypochlorite takes place almost entirely with the magnesium salt-yielding magnesium hypochlorite ($MgCl_2O_2$). It is found, however, that in the electrolysers and tanks a white deposit takes place, consisting of magnesium oxide combined with water—viz., magnesium hydrate—showing that the magnesium hypochlorite has decomposed, forming magnesic hydrate, which precipitates, leaving hypochlorous acid in solution. The action may take place as follows: $MgCl_2O_2 + 2H_2O = MgH_2O_2 + 2HClO$. This is called the Hermite solution. The amount of oxidising power is expressed by the quantity of available chlorine in grammes per litre—the usual working strengths being from five to one gramme per litre of solution. When sewage is mixed with about 5 per cent. of the solution, the offensive smell is instantaneously destroyed and the decomposition arrested for about six days, long enough under ordinary circumstances for the sewage to be well out to sea.

This electrolysed, or Hermite, solution has been subjected to many experiments, and numerous criticisms have been made upon it as to its power of rendering sewage sterile. Sir Henry Roscoe found that a 0·8 gramme solution practically sterilised the liquid portion of sewage, when used in sufficient quantity, and that the solid matters were unaffected. Well, a solution which will thus practically sterilise liquid sewage must, I think, be of great value, and when used in effective quantity tend to benefit any locality by preventing those contagious diseases which are usually developed from sewer gases. Although chemical and sanitary engineers have had this aim—*i.e.*, to completely sterilise sewage—in view, this point has not been attained on the large scale by any of the at present known systems. Hermite solution, however, does the next best thing, for in larger proportions it sterilises the liquid portion, and even in small quantities completely deodorises. This is confirmed by Sir Henry Roscoe's eleventh conclusion—viz., "the Hermite fluid even of 0·25 strength acts as an excellent deodoriser."

This is the point taken up by the Ipswich Corporation. They say, if we can have the sewage deodorised and its decomposition arrested for from three to six days the sewage will be well out to sea, and the nuisances of offensive smells in the town will be entirely done away with. Sir Henry also made experiments as to the stability of the electrolysed solution, and he found that a 0·5 gramme solution lost 90 per cent. of its strength in 24 hours, a 0·75 gramme solution being more stable, losing 34 per cent., and a 1 gramme solution 10 per cent. in the same time. This is very interesting and important, but as regards the working of the system in Ipswich, it is not necessary to take this into consideration, because the moment the electrolysed solution is made it is carried direct into the sewer within two minutes after its production. We have in Ipswich been electrolysing sea-water for three months and treating the sewage. The Sewage Committee directed me to report on its working, so I made daily tests and inspections for about two

Digitized by Google

months. The strength of solution varied from half a gramme to one gramme, according to the flow of sea-water through the electrolysers, the quantity of available chlorine made being fairly constant, and the average being 1·04 gramme per ampere-hour. As to the effects of this solution on the sewage I have no figures to give you, but can give a general idea of its deodorising powers. The difficulties in the way of sewering and treating sewage in Ipswich may be explained in the borough surveyor's own words: "To dispose of the sewage of Ipswich, either by irrigation or by intermittent filtration, would be attended with considerable expense. The town is divided by the River Orwell, and, as is frequently the case with towns so situated, the longitudinal falls are very slight, while the lateral falls are very great. The fall from the one end of the sewer to the other is only 8ft., so the flow is not very rapid, whilst, taking a section of the town laterally, there is plenty of fall, and, in consequence, a rapid current into the main sewer. On this account the experiments with the electrolysed solution were made on the main sewer, and at present the solution is running in the sewer at Handford-road in close proximity to the beginning of the main sewer. The result is complete deodorisation of the sewage throughout a long length of the sewer. For a distance of 700 yards free chlorine can be instantly detected by test papers, and for a distance of 1,760 yards the chlorous smell is perceptible, although insufficient to have any action on the test paper. Not only does the main sewer receive the arterials, but it receives the drainage of several slaughter-houses and breweries containing much organic matter. Below Church-street, St. Clement's, there is such a great increase in the quantity of sewage that the results were doubtful. On several occasions, however, samples taken from the outfall were without smell and kept two days, and in one instance it kept four days. If the amount of electrolysed solution, or its strength, could have been increased, the sewage at the outfall would certainly have been completely deodorised, if not sterilised. This is a point which I hope the Sewage Committee will aim at, and when putting the plant permanently into the new buildings that they will have sufficient electrolysers and power to produce enough fluid to deodorise all the sewage of Ipswich and have some to spare for flushing or washing infected areas. I noticed in some of my early morning inspections, when the flow of sewage was at its minimum, that the deposit in the sewer was bleached nearly white by the action of the electrolysed solution. This process has not been going long enough to allow me to obtain any statistics as to the health of the borough or the death-rate, compared with previous years and with other towns; but this I am sure of, that where the sewage has been treated no complaints have been received as to offensive smells. I am confident that any town that adopts this process, which will boldly erect plant to produce more than enough of the electrolysed solution, will be spending money well, and in time will feel the benefit by increased health of the inhabitants, and also by having a lower death-rate. This is what I have suggested Ipswich should do, so that in a year or two, when we are able to make comparisons, we will find a reduction in the death-rate. Such a result will make the process cheap at any price."

AN IMPROVED HALLWACH'S ELECTROMETER.*

In a previously described quadrant electrometer† the author (W. Hallwachs) succeeded in eliminating the principal evils arising from water damping, and obtained constant sensitiveness. The instrument had, however, an inconveniently small damping, and the suspension was not sufficiently free from viscosity. This occasioned errors, amounting to 0·2 per cent. of the potential, if complicated corrections were omitted.

In the present instrument these defects are overcome. Magnetic damping was first tried, as in many existing forms of electrometer, both by fixed magnets and moving conductor, and *vice versâ*; but the instrument thereby either lost its important property of being unaffected by external magnetic disturbances, or caused external disturbance itself. Air damping was therefore to be preferred, and it was found possible to construct an instrument in such a way that the deflections were not influenced by the electrostatic action of the damping vane and chamber. The damping can be regulated, so that any degree of approximation to complete aperiodicity can be obtained. A sufficiently torsionless suspension of platinum wire came to hand, when experiments were being made with silvered glass and quartz fibres, which were found to have too high a resistance for many electrometer methods, and were also more brittle than the platinum. The air-damped electrometer, with the new suspension, enables one to compare potential differences with an error of only a few parts in 10,000. On account of the large damping, which reduces vibration, the instrument can be used in places where the magnetic and other disturbances would preclude the use of sensitive galvanometers.

The measured torsion moment is given by a $\frac{1}{50}$mm. platinum wire, drawn in a double sheath of silver and copper, the ends of which are attached to small clamping strips with eyes. The upper strip is clamped in the suspending rod *a* (Fig. 1); the lower carries a double loop *b*, for the support of the needle axis *c*. The suspension rod can be fixed vertically, and is of considerable length, to allow for suspensions varying from 10cm. to 30cm. in length. The torsion head is carefully insulated from the suspension tube by shellac. The needle is made of 0·06mm. to 0·08mm. thick aluminium foil, fixed in such a manner that it may be removed and replaced by a larger one, to attain the utmost sensitiveness. The lower end of the needle axis carries a loop, *d*, from which the rectangular damping vane *e*, of thin aluminium foil, hangs. This vane swings in a rectangular damping chamber *f*, which can be manipulated through the door *g* without disturbing the instrument. In order to eliminate electrostatic effects in the damping arrangement, the vane and box are maintained at the same potential as the needle, the vane being in direct metallic connection, and the box being supported by a shellaced ebonite pillar *h*, and connected to the terminal *i*, which is connected to the needle terminal. The damping box can be adjusted by the three screws *k*, and by sliding or turning the tube *m*, fitting on the tube *n*, which is fixed to the bottom of the instrument case. In order that the adjustment of the quadrants about the needle should produce no consequent motion of the damping chamber, it must be possible to rotate them, to move them horizontally, and to incline them to the horizontal. To fulfil these requirements the quadrant supports are fixed to a ring *p*, which can turn on a second ring *q*. The latter rests upon three screws *r* in the bottom plate, with sockets in the ring, which is sufficiently large to allow of horizontal motion without touching the support of the damping box.

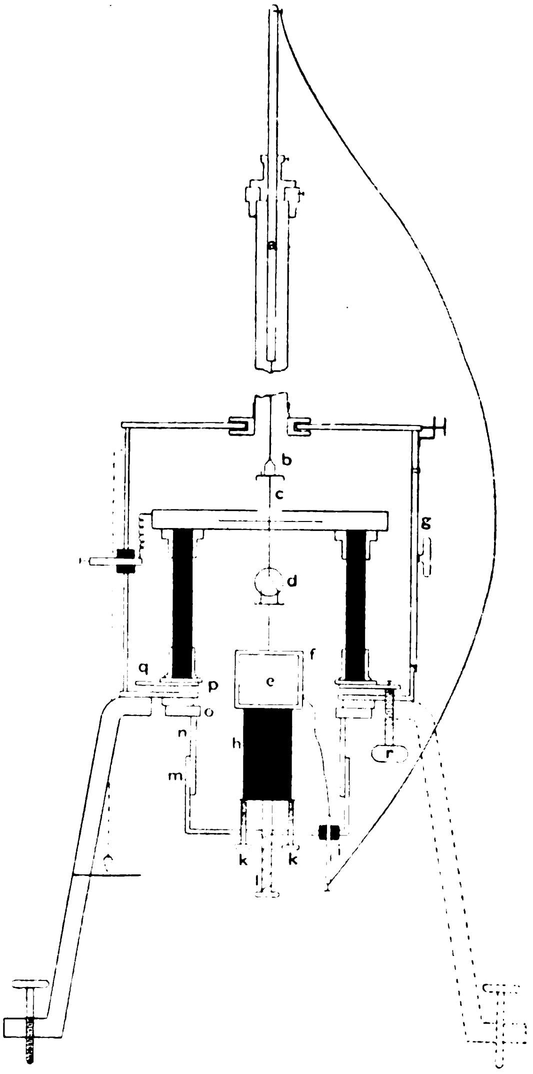

FIG. 1.—Hallwach's Improved Electrometer. Sectional Elevation.

Experiments were made with the object of ascertaining the amount of torsion in the suspension. The first set of observations were made with constant needle potential, and rising and falling

* Abstract from *Wied. Ann.*, No. 5, 1895.
† *Wied. Ann.*, No. 29, 1886.

Digitized by Google

potential differences between the quadrants and the maximum difference between the ascending and descending readings of the same potential was only about 0·03 per cent. The same series of observations was also made, when a constant difference of potential was maintained between the quadrants, and small, gradually increased, potentials given to the needle, which was frequently reversed. The maximum error in this case was also 0·03 per cent. Finally, these experiments were made with variation in the damping, and with constantly maintained potentials, when time readings were taken, all of which show a similar maximum error. The instrument in these observations was used with the smaller needle and a 12cm. suspension, the periodic time varying from 11 to 15 seconds with the damping. With 140 volts needle potential, and a scale distance of 2,000 scale divisions, 1 volt on the quadrants gave 140 scale divisions total deflection when reversed. The sensitiveness could be increased about fourfold by using a longer suspension and larger needle.

In these observations a form of commutator was used which has been found very useful. It consists of a shellac plate (as shown in Fig. 2) fixed on a wood base, and carrying nine iron mercury cups, each having a terminal. The diagram (Fig. 2) shows the connections, N being the needle terminal, E earth, Q_1 and Q_2 the quadrants of the electrometer, $+B_1$ and $-B_1$ the charging battery for the needle, $+B_2$ and $-B_2$ that for the quadrants. Two spider connections are used, of the form shown in the figure, and it will be seen that on turning the left-hand connector through a right angle the needle and earth terminals are reversed with respect to the battery B_1, and that by turning the right-hand connector to any one of its four positions, either quadrant may be connected to either pole of the battery B_2, and may be at the same time either insulated or earthed.

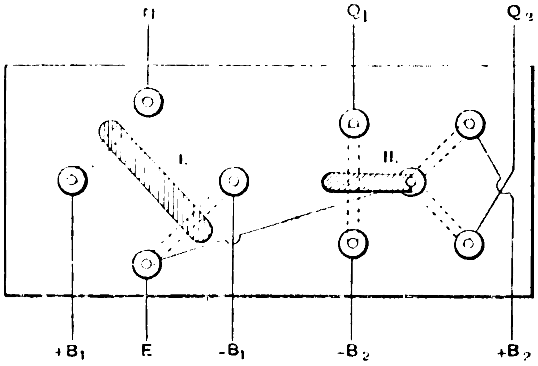

FIG. 2.—Hallwach's Improved Electrometer. Commutator.

LONDON COUNTY COUNCIL.

At the weekly meeting of the London County Council, held at the County Hall, Spring-gardens, on Tuesday, under the chairmanship of Sir Arthur Arnold, it was resolved, on the recommendation of the Fire Brigade Committee, that the tender of Mr. A. W. Jackson, to maintain for two years after the expiry of his contract the electric bells belonging to the brigade, be accepted, the price to be paid for the current year, and for each of the two following years, being £285.

Building Operations.

The Bridges Committee recommended that the consent of the Council be given to the erection of electric lighting buildings on the south side of Bowling Green-walk, in the parish of Hoxton, on the application of the Vestry of Shoreditch, subject to the usual conditions of the Council. The same Committee further recommended that the consent of the Council be not given to the erection of iron water tanks upon the existing one-storey addition at the electricity station, Manor-street, Chelsea, as shown upon the plan submitted by the Chelsea Electricity Supply Corporation (Limited), it being considered undesirable to allow the existing frontage at this part of the street to be disturbed.

The recommendations were agreed to.

National Telephone Company.

The Highways Committee reported that the National Telephone Company had applied for the use of a further 144 square inches of sectional space in the subways of Queen Victoria-street, Victoria Embankment, Shaftesbury-avenue, and Charing Cross-road for the laying of cables. The Company found that the space it now occupied in the subways was insufficient for its requirements, and asked that it might be allowed to occupy double that amount. The Company also desired to connect its cables in the Northumberland-avenue subway with those in the Victoria Embankment subway, and to utilise for that purpose some pipes which were laid down by the Council for the Home Telephone Company, which had been recently absorbed by the National Telephone Company. The Committee thought both requests could be properly complied with, and therefore recommended—"(*a*) That upon the National Telephone Company entering into an agreement, to be prepared by the Council's solicitor, to pay a rent in respect of the user of the subways in Queen Victoria-street, Victoria Embankment, Shaftesbury-avenue, and Charing Cross-road, according to the scale laid down by the Council, and also to pay the outstanding charges (if any) due from the Home Telephone Company in respect of the pipes laid down by the Council for that Company connecting the Victoria Embankments and the Northumberland-avenue subways, the Company be allowed to occupy the further space in those subways now applied for, and also to use the said connecting pipes, upon condition that all work in or about the subways shall be carried out under the supervision of the Council's chief engineer at the sole cost of the Company, and that any damage that may be done in or about the subway in the execution of the work shall be made good by the Company to his satisfaction. (*b*) That it be referred to the solicitor to prepare, and obtain the xecution of, the agreement above referred to."

The recommendations were agreed to.

Size of Transformer Chambers.

Reporting on the appeal of the County of London and Brush Provincial Electric Lighting Company to the Board of Trade against decisions of the Council formally disapproving of the construction of 42 transformer chambers of large size under the public streets of St. Giles and Clerkenwell, the Highways Committee stated that the award of the Board was given on September 12th, and allowed of the construction of 25 of the transformer chambers upon condition that they were constructed in accordance with certain drawings attached to the order, and that there should be no gas pipe within such distance of any box as was equal in feet to the diameter of the gas pipe in inches. The Board further disapproved and disallowed the appeal in respect of the construction of 17 chambers. The Committee regretted the decision of the Board of Trade to allow the construction of these large transformer chambers, but as the ultimate responsibility rested with the Board they had the satisfaction of knowing they had done all in their power for the protection of public interests in the matter.

The County of London and Brush Provincial Electric Lighting Company had given notice, dated August 23rd, of intention to construct 15 transformer chambers in Clerkenwell and St. Luke's, in lieu of the 17 disallowed by the Board of Trade, the proposed position of 12 of them being slightly varied to avoid the special difficulties found to arise in connection with the positions originally selected. The remaining three were in the positions of which the Board of Trade did not approve. In face of the decision of the Board of Trade the Committee did not think the consent of the Council should be refused with regard to the 12 chambers, but they thought their consent to the remaining three should be withheld. Accordingly they had notified approval of the 12 chambers, subject to the conditions stated in the award of the Board of Trade and to the further conditions that the Company should give two days' notice to the Council's chief engineer before commencing any of the chambers, and that they should be constructed strictly in accordance with the plans submitted; they had also directed notice to be served on the Company objecting to the remaining three chambers.

The same Company had also given notice, dated September 13th, of intention, under the provisions of the Wandsworth Order, to construct four transformer chambers in the following positions: at the corner of Colnette-road and Upper Richmond-road; at the corner of Carlton-road and Putney Hill; on Putney Hill near Kersfield-road; and at the Green Man public-house. They recommended that sanction be given to the work.

An amendment, standing in the name of Mr. Thornton, "That the Board of Trade be informed that the Council formally continues its disapproval of the construction of transformer chambers in the thoroughfares of the metropolis," fell through in that gentleman's absence from the chamber, and the recommendation was agreed to.

Loans Completed.

It was reported by the Finance Committee that the loans of £51,000 to the Islington Vestry and of £30,000 to the St. Pancras Vestry for electric lighting installation purposes in those parishes had been completed.

BOOKS RECEIVED.

"Calendar of the Glasgow and West of Scotland Technical College." Session 1895-96. (Glasgow: Robert Anderson.) Price 1s.

"Electrical Measurements." By Prof. H. S. Carhart and G. W. Patterson. (Boston: Allyn and Bacon). Price $2.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of this week Dr. Lodge refers to the "unofficial sentence"—weber-turns = $\frac{1}{4}$ mean volts per cycle—or better expressed—weber turns = $\frac{\text{mean volts}}{4 \times \text{frequency}}$. There seems in some way to be confusion about the value of the constant 4, as Prof. Perry desired to change it to 2π, while Dr. Lodge states that it is dependent on the law of change of induction. May I point out that it is universally true whatever the law of variation may be, and has no connection with a sine function. When I first quoted it in a letter published in your columns on August 2nd, my intention was merely to show the application of one of the terms—viz., "weber-turn"—to a very usual and useful expression for the induced E.M.F. in any circuit—viz., that mean volts = alteration in number of lines of force per second × the number of turns in the circuit. This is obviously the same as my expression, and clearly it is universally true.

I am glad to find that my proposal to make $\mu = 4\pi \times 10^{-9}$ for air, from the expression permeability = $\frac{\text{webers per sq cm.}}{\text{amp. turns per cm.}}$, has been previously advocated by Prof. Perry. It certainly seems to me the simplest way out of the 4π difficulty, and in fact if the large weber and the ampere-turn hold their own, it must be adopted.—Yours, &c.,

University College, Liverpool. F. G. BAILY.

P.S.—Prof. Lodge asks me to notify another slip in his letter on page 725, namely, that in line 11, where he has written "divided" instead of "multiplied."

THE MAGNETIC FORCE DUE TO ANY PLANE CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Prof. Minchin's Paper and M. Colard's letter thereon, the magnetic force at any point in the plane of any plane circuit can be expressed by

$$F = i\int\frac{d\theta}{r},$$

where r and θ are the polar co-ordinates of a point on the circuit, referred to the point considered, and i is the current. This is one of the formulæ included in my Paper brought before the British Association.—Yours, &c.,

October 2, 1895. W. H. EVERETT.

LEGAL INTELLIGENCE.

Pink v. Cambridge Electric Supply Company (Limited).

This action was heard at the Cambridge County Court on the 25th ult., and was brought by Mr. O. F. Pink to recover £20 damages for an accident which the plaintiff contended was due to the negligence of the defendant Company in laying down their electric lighting mains. The accident occurred on May 27th, when the defendant was walking from the Free Library in the direction of Market-hill, and the inside of his right heel caught against one of the electric light boxes. He was thrown heavily to the ground, and when he got up he examined the box and found it at least half-an-inch above the level of the pavement. After evidence had been given on behalf of the plaintiff, Mr. J. H. Barker, the manager of the defendant Company, stated that the box in question had not been moved since June, 1893, when he became manager of the Company. If the pavement near any box was irregular the Company notified the Corporation, but no account for repairing the pavement around this box had been sent into the Company. The lid of the box was, however, taken up last Christmas, but afterwards screwed down again to its former position. Eventually the jury returned a verdict for the defendants, and His Honor (Judge Bagshawe, Q.C.) entered judgment for them with costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions can now be sent in.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 8s. 6d.; Unvarnished, 8s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d.

A SHEET TABLE giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

TENDERS INVITED.—The Lancashire and Yorkshire Railway Company invite tenders for stores for the twelve months ending October 31, 1896. Included in the list of articles required are fog signals, india-rubber, iron castings (hydraulic and water pipes), iron chain, iron hinges, steel, and files, sundry tools, varnish, brake blocks, ironmongery, &c. Further particulars and forms of tender may be obtained at the Stores Department, Osborne-street, Manchester, up to the 5th prox., between 10 a.m. and 4 p.m., and on Saturday between 10 a.m. and 12 noon. Tenders to the Secretary, (Mr. C. W. Bayley), must be sent in not later than 10 o'clock on Monday next.

——— The Great Western Railway Company invite tenders for telegraph instruments, india-rubber goods, copper, iron and steel wire, telegraph ironwork, tools, &c.; electric light carbons, &c. Tenders, to the Secretary, Paddington Station, W., by Monday.

——— The municipal authorities of Tongres, Belgium, invite tenders for the concession for the public and private electric lighting of the town. Tenders to the Administration Communale by 10th inst.

Digitized by Google

Tenders Invited.—The Electric Lighting Committee of the Bedford Urban Sanitary Authority invite tenders for the supply and delivery of 200 cast-iron lamp columns, carriers and globes. Tenders must be sent in to the Clerk (Mr. T. S. Porter) by the 8th inst.

——— The Croydon Town Council invite tenders for wiring, and for supplying and fixing electrical fittings at the New Town Hall, Courts and Free Library. Tenders to Mr. C. M. Elborough (Town Clerk), Town Hall, Croydon, by 4 p.m. on Tuesday next.

——— Tenders are being invited by the municipal authorities of Bucharest, Roumania, for the supply of a number of electric lamps and a quantity of arc-lamp carbons.

——— The municipal authorities of Almodovar del Campo (Ciudad Real Province) invite tenders for the concession for the electric lighting of the town during a period of 20 years. Tenders, to be addressed to the Ayuntamiento de Almodovar del Campo (Ciudad Real), Spain, by the 8th instant.

——— Tenders for the supply of a quantity of telegraph cable and copper wire, in two lots, are being invited by the Direction-Générale des Chemins de Fer, Postes et des Telegraphes, Brussels. Tenders by the 16th instant.

——— Tenders are required for the wiring of the Waverley Market, Edinburgh. Tenders to Mr. Thomas Hunter, W.S., Town Clerk, City-chambers, Edinburgh, by the 12th inst.

——— The Corporation of Newport invite tenders for wiring and for supplying and fixing electrical fittings at the Provision Market and Public Baths. Tenders, addressed to the Town Clerk, Town Hall, Newport, Mon., by the 11th inst.

Tenders Accepted.—The Board of Control, Dublin, received 20 tenders for the installation of the electric light at the Killarney Lunatic Asylum. The amounts varied from £957 to £3,195, and the lowest tender, that of Messrs. Ferguson and Co., has been accepted.

——— Eleven tenders were received by the Great Hall Company, Tunbridge Wells, for wiring the Great Hall for the electric light. The estimates ranged from £86. 18s. to £198. 11s. 5d., and the lowest, that of Mr. E. Powell, has been accepted.

——— The London County Council have accepted the tender of Mr. A. W. Jackson for the maintenance of the electric fire alarms for the Fire Brigade for a further term of two years. The amount of the tender was £285 per annum.

Appointment Vacant.—An assistant in the physical department of the City and Guilds of London Technical College, Exhibition-road, S.W., is required. Salary £100 per annum. Applications to Prof. W. E. Ayrton.

——— The Blackburn Corporation require an assistant engineer at their electricity works. Salary £130 per annum. Applications to the Town Clerk (Mr. Robert E. Fox), Town Hall, Blackburn, by the 19th inst.

Removal.—Messrs. Campbell, Macmaster and Co., consulting engineers and manufacturers' agents, notify us that they have removed to 11 and 12, Clement's-lane, E.C. The firm's telegraphic address is *Duke, London*, and the telephone number will continue to be *2011*.

Dissolution of Partnership.—Messrs. D. J. Callow and W. A. Cloud, hitherto trading as electrical and mechanical engineers, at Pier-place, Strand-on-the-Green, Chiswick, under the style of Callow, Cloud and Co., have dissolved partnership.

Bankruptcy.—A meeting of the creditors of the New British Electrical Installation Contractors (Limited) was held at Worcester on Tuesday. The statement of affairs showed that the gross liabilities amounted to £4,363. 18s. 5d., of which £3,922. 16s. is expected to rank, and the assets are estimated to realise £441. 2s. 5d. As regards contributories, there were 160 Ordinary fully-paid £5 shares, and thus the total deficiency was brought up to £4,722. 16s. An abstract of the Official Receiver's observations on the failure was given in our last issue, and Mr. Millington, who was mentioned as one of the promoters of the Company, has now issued a reply to these observations. Mr. Millington protested against the manner in which the report had been compiled, and its publication seven days before the first meeting of the creditors, and alleged that material facts, favourable to the directors, had been suppressed. Mr. Millington further stated that he had lost a considerable sum by the failure, and was, moreover, an ordinary creditor. A heated discussion then took place, the Official Receiver (Mr. Luke Sharp) stating that he had gone carefully into the Articles of Association, and he had grave doubts whether the debentures would stand. Consequently he thought it better that they should apply for the appointment of a liquidator. This course was, however, not adopted, and the matter was left in the hands of the Official Receiver.

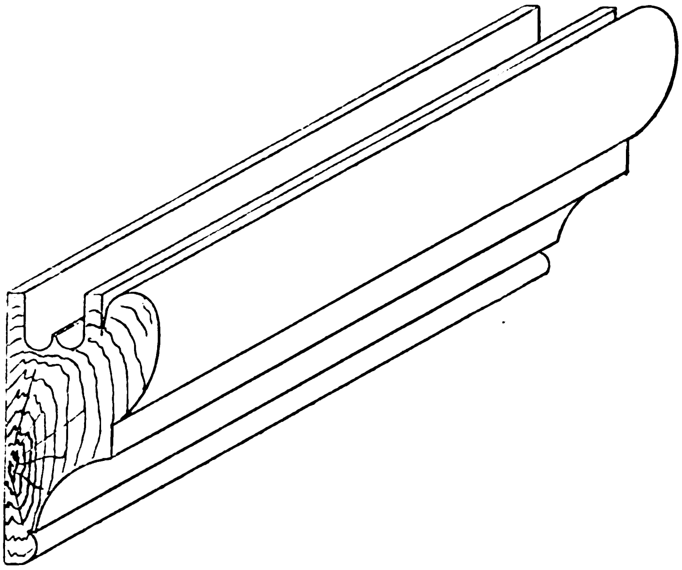
Liquidations.—It has been decided to wind up Lowcock, Hill and Co. (Limited) voluntarily. Creditors must send in particulars of their claims to Mr. A. S. Brewis (the liquidator), 60, King-street, Manchester, by the 28th inst.

Agency.—Mr. D. J. Russell Duncan, formerly senior partner in the firm of Duncan Bros., engineers, Westminster, and late Managing Director of the Steel Pipe Company (Limited), has commenced business at 80, Boulevard Haussmann, Paris, as agent for the sale of machinery, electrical apparatus and specialities of British manufacture suitable for French trade, and also for sale of inventions protected in France.

Drake and Gorham.—This firm inform us that they have been very busy in their installation department for some months past, having at the present moment nearly 30 installations in hand. The firm have been entrusted with the installation of the electric light at "The Lea," Mr. C. C. Wyllie's new house in Surrey, while a similar contract for the lighting of the house of Major the Hon. E. R. Bourke in Great Cumberland-place has also been placed with them.

Safety Tread Syndicate (Limited).—This Company have been appointed contractors to the War Office, Admiralty, and the India Office, for the supply of their well-known safety treads (Mason's Patent).

Electric Wire Picture Rod.—The accompanying sketch represents a picture rod, designed for carrying electric wires around a



room. The rod can, of course, be either of metal or of wood. It has been registered by Messrs. Skegg and Co., of Salford.

Chloride Electrical Storage Syndicate (Limited).—We have received a sheet containing prices and particulars of the new "R" type cell of this Syndicate, which is fitted with a new type of plate. It is claimed for this cell that it can be charged in four hours, thus effecting a considerable saving in the time formerly necessary for charging, and when discharged at a three-hours rate 80 per cent. watt efficiency and 90 ampere-hour efficiency are guaranteed.

Lithanode Electric Storage Company (Limited).—This Company has been formed for carrying on business as electrical engineers, electrical instrument makers, &c. By order of the Court the purchase has been concluded of the Lithanode and General Electric Company's patents, goodwill, plant and stock in trade as a going concern from July 8th last. The Company have also taken over the old Company's works at Westminster, where, for the present, all communications should be addressed. The new firm will continue the manufacture of the now well-known lithanode batteries, &c.

Pneumatically-controlled Switches.—A system of pneumatic control for switches has been developed by Messrs. Seiler Frères, of Paris, and for which Messrs. Julius Harvey and Co., 11, Queen Victoria-street, E.C., are agents. Instead of operating an electric switch directly by hand, this system provides that it shall be thrown into or out of action by means of a pneumatic tube and hand air-compressor, such as a squeezable ball. The advantage claimed for this arrangement is that it enables a single switch to be controlled from more than one point of control, by pneumatically coupling it with several branches of flexible tubing.

"The Engineering Magazine."—The October issue of this magazine is now ready, and maintains its usual high standard both as regards letterpress and illustrations. The subjects dealt with in the present issue (No. 1, Vol. X.) include: "National Supremacy on the Sea," by W. P. Stephens; "The Revolt in Cuba, its Causes and Effects," by a native Cuban; "The Canadian Lumber Industry," by J. S. Robertson; "Architectural Students' Work Abroad," by G. R. Phené Spiers; "Future of the Electric Tele-

Digitized by Google

graph," by P. B. Delany; "The Newhouse Tunnel at Idaho Springs," by Arthur Lakes; "Mountain Railroads in Mining Regions," by James R. Maxwell; "Future Methods of Sewage Purification," by W. L. Hedenberg; "Underflow as Related to Irrigation," by H. V. Hinckley; and "Racial Traits in Machine Designing," by Albert Williams, jun., together with the usual exhaustive Review of the World's Industrial Press. All the back numbers may be obtained at the offices, 1, 2 and 3, Salisbury-court, Fleet-street, London. A complete index to the main articles in the magazine from the commencement in April, 1891, is now ready, and will be forwarded post free on request.

Aberdeen.—The *Aberdeen Free Press* advocates the extension of the electric light mains to the West End, where it is stated many of the residents are anxious to substitute electricity for gas lighting. The work of installing the electric light at Castle Newe, the seat of Sir Charles Forbes, Bart., has just been finished. Two 85-ampere Goolden dynamos and two "Achilles" turbines are employed. A battery of Epstein accumulators has also been installed, and the work of installation was carried out by Mr. V. G. Middleton. Messrs. New and Mayne recently installed the electric light at Brackley House for Sir Allan Mackenzie, and the same firm are at present carrying out an installation at the residence of Mrs. Pickering.

Belfast.—The report of the Electric Light Committee presented at the last meeting of the City Council stated that the increased demand for the electric light necessitated the putting down of some additional machinery, for which they had advertised. The Committee further reported that they were considering the desirability of extending their mains in a few of the principal thoroughfares immediately outside the present area of supply. The report was adopted.

Bermondsey (London, S.E.).—The Capital and Counties Electricity Supply Company (Limited) have notified the Vestry of their intention to apply for a Provisional Order for the district. The matter was referred to the Law and Parliamentary Committee for consideration and report.

Blackpool.—An explosion took place in one of the surface boxes in Church-street on the 26th ult. It is stated that there were unmistakable evidences of coal gas being present. A fault on the circuit was the "exciting cause" of the explosion. Lights were out on the circuit for 55 minutes. The ventholes in the surface-box lids had got clogged up, and thus allowed the gas to accumulate.

Bearpark (Durham).—The Parish Council at their last meeting discussed the lighting question, and the matter was adjourned for the purpose of obtaining the probable cost of lighting the district electrically.

Bolton.—At the last meeting of the Town Council the Gas, Electricity and Street Lighting Committee reported that they had almost reached the limit of the capacity of their present generating plant, and that they would have to make some extensions thereto in the near future. Alderman Miles, in moving the adoption of the report, said that the demand for current continued to increase in a most satisfactory manner.

Bristol.—The Electric Lighting Committee have made out their estimate for the half-year ending March 26, 1896, and it is satisfactory to learn the Committee do not intend to make any claim on the rates for working expenses, interest, or sinking fund, and, moreover, expect to make a small profit on the half-year's trading. There are now about 17,500 lamps connected, as against 8,883 in September, 1894. The Committee have several applications for electric current in hand, and they anticipate that by March, 1896, some 24,000 lamps will be connected up.

Broadstairs (Kent).—At the last meeting of the District Council a letter was read from Poole and White (Limited), asking on behalf of an electric lighting company, about to be formed, if the Council would support their application for a Provisional Order for the district. Some time ago the Council decided to oppose a similar application from the County of London and Brush Provincial Company. After a long discussion, initiated by Councillor Whitehead, it was decided to communicate with both companies on the subject.

Bromsgrove (Worcestershire).—At the meeting of the District Council on Wednesday some correspondence with the local gas company as to the quality of the gas supplied and the price thereof was read. The Vice-Chairman (Mr. H. W. Lewis) said if they could not come to an arrangement with the gas company they should be prepared to adopt temporary measures for lighting the town until they could devise an electric lighting or some other scheme.

Church Lighting.—The Parish Church, Oswestry, is to be fitted up for the electric light at an estimated cost of about £100.

Coseley (Staffs.).—At the meeting of the District Council on Tuesday, the surveyor (Mr. Shackleton) presented an exhaustive report on the public lighting question. If the Council adopted an electric lighting scheme he estimated the cost of plant at £8,700, and the annual up-keep at £1,226. The report was referred to committee for consideration and report.

Derby.—Good progress is being made with the electricity extension works. The Corporation have at present 194 customers for electric current on their books, while several others are waiting to be connected up. The electricity department has been working at a profit for some time past, and such is the popularity of the electric light that it is anticipated further additions and extensions will have to be made in the spring. There is also an increasing demand for current for motive power purposes, and this branch of the department has already become a very important one.

Douglas (Isle of Man).—The Health Committee are to consider and report upon the question of providing an efficient fire-alarm system for the town.

Dundee.—The Finance Committee of the Town Council recommend that steps be taken for the purpose of extending the electric lighting area of the Council.

East Grinstead.—The Urban District Council are greatly dissatisfied with the manner in which they are being treated by the gas company, and at the last meeting of the Council Mr. York moved that, in view of the attitude of the gas company, and the alleged deficiency in the supply and quality of the gas, the Council should enter into communication with Messrs. Owen Pike and Lucas as to the introduction of the electric light. This motion was adopted.

Edinburgh.—The Electric Lighting Committee, at their last sitting, decided to adopt the "Brockie-Pell" arc lamp for the lighting of Charlotte-square, George-street, St. Andrew-square, and the streets leading up to them from Princes-street. It was stated that the former contractors (Messrs. Crompton and Co., Limited) could not undertake to supply the present style of lamp at the old price.——The Cleaning and Lighting Committee have decided to recommend that the West Bow and the Grassmarket should be lighted by electricity and to erect arc lamps at the corners of Picardy-place and London-road. The Committee further recommend that until some definite scheme of extension had been resolved upon, the lighting of Castle-terrace by electricity should be postponed.

Exeter.—At the meeting of the City Council on Tuesday last a motion that the seal of the Corporation be affixed to a conditional agreement for the purchase of the Exeter Electric Light Company's undertaking was passed. It was also decided to make application to the Local Government Board for sanction to borrow £11,000 for electric lighting purposes.

Halifax.—At the meeting of the Town Council on Wednesday, detailed plans were presented by Messrs. Easton, Anderson and Goolden for the construction of electric tramways in the town on the overhead system. Two routes were suggested, one from the railway station by Horton-street and Commercial-street to King Cross, and the other from the Grand Theatre to Haley Hill and Boothtown. The road work is estimated to cost the Corporation £12,500 for 3½ miles, while the rough estimate for working and electrically equipping an overhead system is put at £18,500. The matter was, after a brief discussion, postponed till the November elections had taken place.

Harrogate.—At the meeting of the Town Council on Tuesday, it was decided to apply for sanction to borrow £35,000 for electric lighting and other purposes.

Harrow.—At the last meeting of the District Council it was stated that the Board of Trade would allow the transfer, by the Council, of the Harrow Provisional Order to the Harrow Electric Light Company (Limited).

Heaton Norris (Stockport).—At the last meeting of the District Council the Chairman stated that he thought the time had arrived when the Council should take steps to consider the question of lighting the district by electricity, and he moved that a sub-committee be appointed to immediately consider the matter. Mr. Everatt suggested that the Committee should be empowered to obtain information from other Councils who had obtained Provisional Orders. The motion and amendment were adopted.

Higher Commercial Education.—A free lecture, explaining the objects of the lectures and classes arranged for the ensuing winter by the London Chamber of Commerce, in connection with the London School of Economics and Political Science, will be delivered by Mr. W. A. S. Hewins, M.A., at Botolph House, Eastcheap, E.C., on Monday next, at 6:30 p.m. Sir Albert K. Rollit, D.C.L., M.P., will preside.

Limerick.—The Town Council some time ago passed a resolution in favour of the introduction of the electric light, but beyond this they have done nothing to comply with the terms of their Provisional Order, which expires early in 1896. The Board of Trade have now written for the second time, asking what progress they had

Digitized by Google

made in the matter, and a special meeting is to be held on Tuesday next for the consideration of the question.

Liverpool.—At their meeting on Wednesday the City Council agreed to the recommendation of the Special Lighting Committee that a further agreement be made with the Liverpool Electric Company to complete the purchase of the Company's undertaking, works and property, in accordance with the agreement already made, within six weeks from the date of an Act of Parliament authorising the sale to the Corporation, provided such Act is passed in the year 1896.

Llanberis.—It is stated that fair progress is being made with the construction of the electric railway leading up to the summit of Snowden. There is, however, no likelihood of its being ready for traffic this year.

Londonderry.—At a recent meeting of the Lighting Committee Alderman Pollock introduced the question of private lighting. He said a very large number of ratepayers were most desirous to have private lighting introduced, and he knew that several churches were anxious to obtain electric current. Alderman Fleming agreed that the electric light was needed in the churches, as the gas was very bad and deficient in illuminating power, and he hoped the Chairman would call a meeting to consider the matter, when Alderman Pollock would probably have some figures to put before them. The further consideration of the matter was deferred for a fortnight.

Maidstone.—At the last meeting of the Town Council the Technical Education Committee presented a report recommending the borrowing of a further sum of £1,300 for the Technical Schools. This additional sum was required for the electric lighting of the building and for fittings and apparatus. The matter was, however, referred back for further consideration.

Northampton Institute.—This Institute, which is now nearing completion, will be lighted throughout by electricity. The Committee have decided to put down their own generating plant. The entire installation is estimated to cost about £3,000.

Pembroke (Dublin).—The Town Commissioners have under consideration the question of the adoption of a combined electric lighting and refuse destructor scheme, and intend to apply for a Provisional Order.

Sheffield.—As the lease of the Sheffield Tramways Company will shortly expire, the Town Council will be called upon to consider the question of either renewing the present Company's lease or of taking the management of the tramways into their own hands. In view of the latter event, the *Sheffield Independent* has been collecting information from various quarters as to the best system of traction to be adopted by the Council, and in its issue for the 27th ult. an abstract of this information is given.

Stafford.—The formal opening of the electric light works takes place on the 15th inst.

St. Helens.—Mr. F. H. Tulloch, M.I.C.E., held a Local Government Board inquiry on Tuesday last into the application of the Corporation for sanction to borrow £10,000 for electric lighting purposes. The Town Clerk (Mr. W. J. Jeeves) gave particulars of the scheme, and there was no opposition to the application.

St. Pancras.—The Vestry have reconsidered the matter of allowing a service pipe to be laid from the London Hydraulic Company's main to premises in Charlotte-street, and have now given their consent to the application, on condition that the power is only used for a lift. The Vestry will shortly be able to supply current from the King's-road station, as the work of equipping is now practically complete.

Sunbury-on-Thames.—The engineer (Mr. Anstie) has presented a report to the District Council on a suggested scheme of sewage pumping by electricity. The estimated cost of the electrical machinery is put at £6,250. The matter is to be further considered at the next meeting of the Council.

Swansea.—The report recently presented by the Electric Lighting Committee on the proposed joint electric lighting and refuse destructor scheme was considered by a specially convened meeting of the Town Council on Wednesday. The subject was discussed at great length, and, after various amendments postponing the matter were defeated, the report was adopted.

Telegraphic Communication in Siberia.—It is stated that a telegraph line is to be constructed between Bachta and Tchugutschesk, Siberia, by which telegraphic communication with Western China will be facilitated.

Telephone Extensions in Germany.—The telephone exchange at Essen was recently fitted up with multiple switchboards (for 6,000 subscribers), which have been manufactured and erected by Messrs. Mix and Genest (Limited), of Berlin, for the German General Post Office. The result is that the telephone service has been greatly improved, as attention is more prompt and less noise is noticeable at the exchange. The neighbouring towns of Dortmund, Bochum, &c., had previously been fitted up with similar switchboards, and the work had given great satisfaction, thereby accelerating the transformation of the old exchange at Essen into one equipped with the most modern fittings.

Torquay.—The report of the Electric Lighting Committee will be presented at the next meeting of the Town Council.

Warehouse Lighting.—Messrs. Arnott and Co.'s new premises in Prince's-street, Dublin, will be lighted throughout by electricity.

Willesden (London, N.W.).—At the last meeting of the District Council some members urged that an arrangement should be come to with the Hampstead Vestry for supplying electric current for lighting both sides of the High-road, Kilburn. It will be remembered that one side, being within the area of the jurisdiction of the Hampstead Vestry, is already lighted electrically. One member said it would look exceedingly bad if there were only gas lights on one side of the road and electric light on the other.

Woking.—A meeting of ratepayers in the St. John's ward was held on Friday last to consider the lighting question, and after a long debate a motion that the ward be lighted by electricity was carried. The arrangements for giving effect to this vote were left in the hands of the representatives of the ward on the District Council.

Worksop.—At the last meeting of the District Council, Mr. Nash's proposal to form a company for the purpose of supplying electric current for public and private lighting in Worksop was approved. It is reported that many of the principal ratepayers and shopkeepers in the district would be inclined to take current if it were available.

Yeadon (Yorks.).—At a meeting of ratepayers on Friday last, the question of the electric light was again discussed. The electrical engineer (Mr. F. H. Medhurst) whom the District Council had engaged to advise them on the tenders sent in, recommended the acceptance of the Brush Company's scheme. The matter was debated at great length, but no decision was come to, and the meeting was adjourned for three months.

York.—Electric lighting matters do not seem to make much headway in this city. At the last meeting of the Streets and Buildings Committee the city engineer reported that he hoped to have a definite reply from Mr. Preece with regard to his proposed report on the electric lighting of the city before the next meeting of the Committee. It was also reported that several communications had been received from various electrical engineers offering their services as consulting engineers to the City. The York Provisional Order will shortly expire, and the Board of Trade recently wrote to the Council, asking them what steps they had taken to carry out the provisions thereof, and, in reply to this letter, the Town Clerk sent a *résumé* of the various attempts which the Council had made to "find" a suitable electric lighting scheme.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

14,481. POOLE and LOWRY. Imitation candles for electric lights.

COMPANIES' MEETINGS AND REPORTS.

Froggatt's Electric Lighting Company (Limited).

The first annual general meeting of this Company was held at Winchester House, Old Broad-street, on Monday last, under the presidency of Mr. A. de Murrieta.

The SECRETARY (Mr. Arthur S. Hiley) having read the notice calling the meeting,

The CHAIRMAN said: It is a very great disappointment not to be able to meet you with a more favourable report of the past year's business of the Company, but in all new businesses the first year is very difficult, and more especially we have found it full of difficulties, particularly in regard to the lighting of public vehicles, which is a branch to which we have specially devoted ourselves. However, after the experience we have gained, we feel confident now of overcoming all obstacles, and we are now actually lighting under contracts the London Tramways (over 500 lights), the Glasgow Corporation Tramways (over 800 lights), and omnibuses for Messrs. Ball Bros. (88 lights), Tillings (45 lights), and a few others. We have also sold apparatus for lighting six omnibuses to the Isle of Man Tramways and Electric Power Company, who are trying our system. The extension of this business, however, requires very serious consideration, owing to the large amount of capital it absorbs, the very rough treatment our batteries are exposed to, and the unreliable class of men we are obliged to employ for night work, and particularly in bad weather. The latter difficulty, however, we have got over in the case of the South London Tramway Company, by an arrangement lately made with them by which their own staff now do this work, and we hope shortly to make a similar arrangement with the Glasgow Corporation. Our lighting has attracted a great deal of attention, and we have constant inquiries on the subject, and applications for agencies both from abroad and the provinces. We are now devoting more attention to portable lights for houses, cycles, travelling lamps, and policemen's and postmen's lights, for all of which we think there is a growing demand. Another very important field for lighting has been started by us, but I do not think it advisable to refer to it more in detail here; but I may mention that a very influential firm connected with this particular business has been so much impressed with what we have already done that it has approached us with a view to acquiring the agency for the whole of this branch of the business. A considerable amount of friction has on several occasions arisen between the Directors themselves and between the Board and the management. Under these circumstances we think it very advisable that the shareholders should appoint a committee to confer with the Directors with a view to reorganising the Board and the management generally. The Chairman concluded by moving "That the report be adopted," which was seconded by Mr. McGill, and which was agreed to.

In answer to a question, the SOLICITOR (Mr. H. Keeble) said that he had advised the Chairman that the subject of the appointment of the committee could not be entered into that day, as it did not come within the scope of the meeting. The committee would have to be appointed at an extraordinary general meeting summoned for the purpose.

The CHAIRMAN said that they would call such a meeting within about a month.

The retiring Director (Mr. C. de Murrieta) and the auditors (Messrs. W. P. Eldrid and Co.), were re elected, and the usual vote of thanks to the Chairman terminated the proceedings.

Willans and Robinson (Limited).

The third half-yearly report of the Directors of this Company, to be submitted at the meeting to be held at the Cannon-street Hotel, London, E.C., on Tuesday next, the 8th inst., at 3 p.m., states:—

The engine orders for the half-year ended June 28th amounted to 12,832 I.H.P., against 10,315 in the corresponding half of 1894, and 9,290 in 1893 (old company). As previously pointed out, the Company has had great difficulty in keeping pace with its orders, and the fast increasing demand for the Willans engine, though encouraging for the future, is only a source of embarrassment in the present, and must continue to be so until the new works at Rugby are completed. After writing off as depreciation from plant, patents, &c., the large sum of £3,762. 0s. 3d. (exceeding by nearly £900 the amount written off last half-year), the balance to the credit of profit and loss account for the half-year is £10,614. 2s. 7d. The Directors propose that dividends be paid at the rate of 6 per cent. per annum upon the Preference shares, and at 7 per cent. per annum (as before) upon the Ordinary shares, which will together absorb £6,586 5s. 2d. It is proposed to carry £2,500 to the reserve fund, which will then amount to £5,146. 9s. 11d., and to carry forward a balance of £319. 10s. 2d.

Arrangements for the manufacture of the Willans engine upon the Continent, under licence, have made further progress. For the first time "Royalties receivable" appear in the accounts, and this source of revenue is likely to increase. Licences for certain countries have been granted upon satisfactory royalty rates, and in connection with these licences certain cash payments have also been made. After writing off all expenditure incurred in arranging the licences, the sum of £3,632. 12s. 1d. remained to the credit of profit and loss, which enabled the Directors (as already stated) to write off about £900 as increased depreciation, and to reserve an equal amount in the valuing of other accounts, as well as to carry an unusually large sum to the reserve fund.

Digitized by Google

The balance of the shares authorised to be issued has been taken up. The applications for these shares considerably exceeded the number to be allotted. The entire debenture debt, amounting to £9,910, was paid off as from March 31st last, but many of the debenture-holders applied for and were allotted shares in lieu of the cancelled debentures. It was thought desirable to perpetuate the system of workmen's debentures, which had been for some years in force, and workmen's bonds, to the amount of £1,080, were issued to the holders of cancelled workmen's debentures, bearing the same interest as the latter.

The new works at Rugby are making satisfactory progress, though it is anticipated they cannot commence to add to the out-turn from the Company's workshops for another six months. Contracts for buildings, &c., to the amount of £18,700, have already been placed.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, *pages 304-332, &c., &c.*

UNIVERSAL ELECTRIC CARRIAGE SYNDICATE (LIMITED).—This Company was registered on September 25th, with a capital of £5,000, in £1 shares, to carry on in the United Kingdom or elsewhere the business of electricians, electrical engineers, mechanicians, manufacturers and owners of electrical vehicles and carriages, workers of and dealers in electricity, electrical machinery, appliances, apparatus, &c.; to carry into effect an agreement with Walter C. Bersey, electrical engineer, to construct, purchase, equip, maintain and work omnibuses, vans, and other vehicles for the carriage of passengers and goods, and to make experiments in and give public exhibitions of electric force, traction, and lighting, and of electrical appliances, &c. The subscribers, with one share each, are: D. C. Miller, J.P., C. N. Stewart (mechanical engineer), R. J. Hinton, Walter C. Bersey (electrical engineer), G. E. Thompson, R. Wheeler, and R. H. Wheeler. The first Directors are: D. C. Miller, J.P., R. J. Hinton, C. N. Stewart; and (after allotment) Walter C. Bersey will act as Managing Director.

BABCOCK AND WILCOX (LIMITED).—The annual return to September 24th has been filed. The nominal capital is £240,000, divided into 14,000 Ordinary and 10,000 Preference shares of £10 each. The whole of these shares have been taken up, and 4,666 of the former and 3,333 of the latter have been issued as fully paid. The full amounts have been called on the remaining 9,334 Ordinary and 6,667 Preference shares.

CHILI TELEPHONE COMPANY (LIMITED).—The annual return to August 13th has been filed. 44,000 shares have been subscribed for out of a nominal capital of £250,000, in £5 shares, and the full amount has been called and paid.

COLUMN PRINTING TELEGRAPH SYNDICATE (LIMITED).—The annual return to August 13th has been filed. 289 £50 shares have been taken up out of a capital of £25,000, and 100 of these have been issued as fully paid. The full amount has been called on the remaining 189 shares.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE (*now* **MANUFACTURING**) **COMPANY (LIMITED).**—The annual return to June 20th was not filed until September 10th. The nominal capital is £234,938, divided in 47,363 £6 per Cent. Preference shares and 75,150 Ordinary shares of £1 each, and 224,850 Ordinary shares of 10s. each. All of the last-named class have been subscribed for, and the full amount paid thereon.

D.P. BATTERY COMPANY (LIMITED).—The statutory return to September 23rd has been filed. The nominal capital of £10,000 is divided into 4,996 "A," 4,996 "B," and eight "other" shares, all of £1 each. The whole of these have been subscribed for, and the full amount has been called on the "other" shares, while calls, amounting to 14s. per share, have been made on the "A" and "B" shares.

LONDON AND LANCASHIRE ELECTRIC AND ENGINEERING COMPANY (LIMITED).—The annual return to July 29th has been filed; 1,987 shares have been taken up out of a capital of £20,000, in £5 shares, and of these 1,000 have been issued as fully paid. A call of £2 per share has been made on the remaining 987 shares.

NATIONAL COMPANY FOR THE GENERATION OF ELECTRICITY BY SECONDARY GENERATORS (LIMITED).—The annual return to August 28th has been filed. The nominal capital is £500,000, in 3,000 Preference and 47,000 Ordinary shares of £10 each. 2,669 of the former and 20,000 of the latter have been taken up, and 1,000 Preference and all the Ordinary have been issued as fully paid. The full amount has been called on the remaining 1,669 Preference shares. 100 shares have been forfeited.

TELAUTOGRAPH COMPANY (LIMITED).—The statutory return to August 6th has been filed. The nominal capital is £42,000, in 16,000 Preference and 26,000 Ordinary shares of £1 each; 8,492 of the former class have been subscribed for, and a call of 10s. per share has been made on 8,485 of these.

WALSALL ELECTRICAL COMPANY (LIMITED).—The annual return to September 19th has been filed. Of a nominal capital of £10,000, in £10 shares, 683 shares have been taken up, and of these 200 have been issued as fully paid. The full amount has been paid on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, $30\frac{11}{16}$d. per oz. (Oct. 3rd). Consols ($2\frac{3}{4}$ per cent.) $107\frac{5}{8}$—$107\frac{3}{4}$ for money, $107\frac{5}{8}$—$107\frac{3}{4}$ for account (Oct. 3rd); $2\frac{1}{2}$ per cent. 106—$106\frac{1}{4}$. Stock Exchange Settling Days: Consols, Nov. 1st; Stocks and Shares Continuation Day, Oct. 14th; Ticket Day, Oct. 15th; Pay Day, Oct. 16th; Mining Shares Carry-over Day, Oct. 12th.

BELL'S ASBESTOS COMPANY (LIMITED).—An extraordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel on Friday last, when the resolution as to the division of the existing £5 shares of the Company into five £1 shares, passed at a former meeting, was confirmed.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—An extraordinary meeting of the shareholders of this Company was held at the offices, 14, Dale-end, on the 26th ult., when the resolution authorising the further issue of 10,000 shares of £5 each referred to in our last issue was approved.

CHARLES CAMMELL AND CO. (LIMITED).—The Directors of this Company have decided to pay an instalment on account of dividend for the present year of £2 per share on the Ordinary, and 10s. per share on the "A" and "B" shares.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—This Company's traffic returns for the week ended September 29th were £823, against £881 in the corresponding week of 1894, a decrease of £58. The total receipts for the half-year amount to £10,971, against £11,119 for the corresponding period of 1894, a decrease of £148.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of September, 1895 were £2,072 against £1,898 in the corresponding period of last year.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Board of Directors of this Company have resolved to pay an interim dividend of 2s. per share, free of income tax, being at the rate of 2 per cent. per annum, for the quarter ended September 30th last. The dividend is payable on and after the 24th inst.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company on Wednesday declared an interim dividend, for the quarter ended June 30th last, of 2s. 6d. per share, free of income tax, payable on the 15th instant. The share register will be closed from the 7th to the 14th instant, both days inclusive.

EVERED AND CO. (LIMITED).—The Directors of this Company have declared a half-yearly interim dividend at the rate of $7\frac{1}{2}$ per cent. per annum.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 1s. 3d. per share.

HAWAIIAN TRAMWAYS COMPANY (LIMITED).—At the meeting of this Company on Monday last the Chairman (Col. C. M. Davidson), in moving the adoption of the report, said in 1890 they obtained permission from the Legislature to use electric traction, but up to the present, although they had been watching the development of electric tramways, they had been unable, owing to the expense involved, to recommend its adoption to their shareholders. In America electric traction was greatly used, and no doubt in many instances it had an advantage over horse traction. There was, however, a desire to introduce electric traction on their tramways, and they were making inquiries as to the cost of conversion, &c. It was very difficult to obtain correct details as to renewal, as electric tramway accounts were not yet perfectly clear under this head. They would wish to do the work themselves—to convert, to run, and to renew; but while doing this they must be assured that their shareholders would receive a benefit as well as the travelling public. When they had the whole information ready they would then call a meeting of the shareholders. The report and accounts were adopted.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the six months ended June 30th last at the rate of 6 per cent. per annum on the Preference and $7\frac{1}{2}$ per cent. on the Ordinary shares.

LEIPZIGER ELEKTRISCHE STRASSENBAHN-GESELLSCHAFT.—This is the title of a Company which has just been formed by the Allgemeine Elektricitäts-Gesellschaft in conjunction with several well-known German banks for the erection and working of an electric tramway at Leipzic. The capital of the Company is to be £300,000.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 29th inst. amounted to £1,266. The amount for the corresponding week last year was £988; increase, £278.

REUTER'S TELEGRAM COMPANY (LIMITED).—The Directors have declared an interim dividend at the rate of 5 per cent. per annum, free of income tax, for the half-year ended June 30th last, payable on the 9th inst.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a settling day in, and to grant a quotation to, 9,104 fully-paid £10 shares and 207,649 £2-paid shares of the Central London Railway Company (Limited); and also to appoint a settling day in the shares of the Smelting Company of Western Australia (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 27th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,249.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 908. [No. 24. Vol. XXXV.] FRIDAY, OCTOBER 11, 1895. PRICE SIXPENCE.

NOTES.

There is a tone of old-world imperial largesse about the festal arrangements by which the Directors of the Bristol tramways intend to celebrate the public opening, on the 14th inst., of the electric tramway between Bristol and Kingswood. One almost expected to find the list of festivities terminating with the announcement of a hecatomb. Not only will there be the usual opening ceremony, and a banquet to "a number of leading scientists of the country" and other important personages; but local shareholders are to be given an "opportunity of publicly testing the advantages of an electric car," whatever the process may consist in; and then, most beneficent of all, "a substantial dinner will be provided for 1,200 aged and deserving poor, selected from the localities through which the line goes, and after the repast each person will receive a ticket which will give the holder the privilege of a free ride." We are assured that only really deserving persons are to be the recipients of these benefits. This is bounty indeed; and the only doubt which exists in our mind is, as to what class of aged and deserving poor deserves, after a "substantial repast," to be carted freely about on a tramcar.

We have received an exceedingly lucid pamphlet, written by Mr. T. H. Brooke Hitching, of the Marylebone Vestry, and entitled "Cheap Electric Light for Marylebone." It is needless to say that, according to Mr. Hitching, the way to obtain this desideratum is to parochialise the electric supply, and employ dust "utilisers." For our own part, although we naturally desire to see electric lighting progress, we have not as yet found ourselves able to place entire trust in the alluring percentage profits, such as the 7 per cent. at St. Pancras, which have been so disinterestedly worked out for so many municipal concerns, and we shall feel more enthusiastic about refuse "utilisers" as aids to electric lighting when there has been more experience of them in that capacity. Mr. Hitching, in his eagerness to prove the advantages of the scheme he advocates with so much force and ingenuity is scarcely fair to the Company which is at present engaged in supplying the electric current to Marylebone. To talk of £500,000 as "immense" capitalisation for a concern whose district covers an area of nearly five square miles is mere rhetoric. Again, who but Mr. Hitching would consider a company which earned 5 per cent. *gross* profit as being "in a very prosperous condition"? Before a competitive municipal electric supply is put in hand in Marylebone it is to be hoped its supporters will take a more sober view of its possible profits; it tends more to the genuine advancement of electric lighting to make 5 per cent. where only 3 per cent. was anticipated than to reverse the process.

Prof. Perry describes in our columns this week a wattmeter in which any error due to lag is completely avoided in a simple manner. The use of such an instrument may prove advisable in some cases, although, as Prof. Perry points out, an ordinary dynamometer-wattmeter is quite accurate enough for most purposes, if a large non-inductive resistance is placed in series with the pressure coil. There are, however, two disadvantages about the new form of instrument. In the first place, its accuracy depends on the adjustment of the two oppositely wound coils, each of which carries a heavy current; and it would appear that a slight shift of one of the wires leading up to the coil would be enough to introduce a perceptible error. A more serious objection is due to the fact that whereas the magnetic effect, and hence the sensibility of the instrument, depends on the difference of the currents in the two opposing coils, the space occupied by the coils is determined by the necessity for providing for the two large and nearly equal currents. Thus if one of these is 30·1 amperes and the other 30 amperes the magnetic effect depends on the difference of 0·1 ampere, and many turns of wire will be required to produce an appreciable magnetic effect. But the wire on each of these turns must be thick enough to carry 30 amperes. Hence the space occupied will be disproportionately large.

The Paper by Herr Peukert, a brief extract of which we give in another column, makes certain assertions and describes certain experiments to prove them. The experiments and assertions relate to the fact that in a bar of iron magnetised by a coil at the centre, the lines of force emerge into the air at all points along the bar and not only at the ends; and to the fact that eddy currents induced in the bar cause a lag in the phase of the magnetisation, which increases as the distance from the central coil is increased. The truth of these assertions is undeniable and the record of the experimental verification of the first has probably been lost in the mists of antiquity, while the second phenomenon was demonstrated by Trowbridge some three years ago, and in various forms by

Digitized by Google

other experimenters, besides being an obvious deduction from Prof. ELIHU THOMSON's magnetic repulsion experiments; it is, moreover, an integral property of more than one alternating current meter. But Herr PEUKERT proves too much, for he shows that the effect is produced in laminated iron to about the same extent as in a solid iron bar, though he gives no explanation of this interesting discovery. The accuracy of his curves of $d\,N/d\,t$ must be doubted, since they show a much larger area on one side of the zero line than on the other, and his explanation that this is due to residual magnetism is difficult to believe. It would require an initial magnetisation of altogether impossible amount, since the readings for a single curve extend over many cycles.

SOME rather extravagant and unintelligible claims have been made on the Continent for what are there commonly called "bi-metallic" conductors; to wit, wires, the core of which is of one metal and the sheath of another. So far as these claims relate to the superiority of such compound conductors for the purposes of military telephony, they are conclusively disposed of by the experiments carried out by the officials of the German Post Office, an account of which will be found elsewhere in the present issue. It is evident that the simple secret of success, when running bare wires along the ground to meet temporary emergencies, lies, so far as the line is concerned, in the employment of fine wires, light wires, and mechanically strong wires. Not only, of course, do great lengths of such wire mean small weight, and occupy little space when coiled, but the wire presents but a small leakage surface, sinks but little into the soil, and is not easily put *hors de combat*. Possibly rusty pianoforte wire would prove as good as anything for the short lines and rough-and-ready transmission required in the field.

ELECTRICAL engineers will have no difficulty in perceiving that the results of any reliable experiments on the transfer and radiation of heat from metallic plates, with variously arranged surfaces, are useful in more than one field of practical work. It is not only the boiler maker who wants to know whether any advantage is to be derived from the attachment of ribs and other extensions to the exterior or interior surface of a heat-transmitting plate. The obvious instance of hot-water, hot-air or steam pipes for heating buildings will occur to everyone's mind; and no doubt many will also remember that an attempt has been made to cool internal combustion engines in a similar manner. Within the province of directly electrical work, two chief classes of apparatus are concerned—namely, electrical radiators and thermopiles. In the first-named class the metallic surfaces have the heat generated practically within their mass; or, at any rate, the effect is substantially the same as if it were thus generated. But, after generation, this heat has to pass through the thickness of the radiating plate and then be diffused from a suitable surface. The suitability of the surface depends upon the coefficient of emissivity—as to whether the surface is dull or bright—on the facilities for convection air-currents, and on the extent and contour of the surface. In the second class mentioned, a thermo-electric generator, to be practically useful, must be capable not only of absorbing heat rapidly at the hot junctions, but also of dissipating it with facility from the cool junctions; and it will readily be seen that both these effects are influenced by the arrangement of the heat-absorbing and heat-dissipating surfaces.

THERE is, therefore, a direct interest for electrical engineers in the "Experiments on the Transfer of Heat through Plates with Variously Arranged Surfaces," which Mr. WILLIAM G. WALKER described before Section G, at the recent meeting of the British Association. Mr. WALKER's Paper is a useful contribution to the already voluminous literature of this subject; and a reprint will be found in our columns this week. The author has restricted his researches mainly to the influence of radial internal and external metal ribs, attached to a metallic cylinder in such a way as to oppose their thin edges to any convection currents which might be set up either within or outside the cylinder. He has investigated the influence of these ribs under various conditions; namely, when the cylinder—filled with cold water—is caused to absorb heat from steam, and when it is subsequently caused to radiate out that heat into the air, or to pass it into a tank of water in which the heated cylinder has been immersed. The results are given in a set of curves and tables. In face of the results of tests that have been made from time to time, as to the effect of ribs and conducting rods of copper on the water-side of the crown, and flue surfaces in boilers, the marked inactivity of the internal ribs is a matter for some surprise. The sluggishness of the external ribs, when steam is permitted to condense upon their surfaces, is also a matter of interest, in view of the researches of BRYAN DONKIN and others on the influence of moisture films on the conductivity of steam cylinder liners. We venture to suggest that the influence of moisture films might be eliminated by employing superheated steam or highly-heated air, in place of saturated steam, the water in the cylinders being replaced by some liquid, such as oil or melted paraffin wax, which, at a sufficiently high temperature to start with, would entirely obviate condensation upon the metallic surfaces.

AN interesting description of the electrical equipment of a large coal mine, near Pittsburg, U.S.A., will be found in our columns this week. Electric power, generated in a machinery house near the pit's mouth, is transmitted to the workings, where it is used for coal-cutting, haulage and lighting. Only a portion of the haulage—namely, that over the main tracks above and below ground—is worked electrically, mules being employed to do the gathering and distributing. The main haulage locomotives are of the single-motor, four wheel type, running on 42in. gauge, and developing nearly 4,000lb. draw-bar pull at eight miles an hour. The coal-cutters, it will be observed, have exposed commutators and brushes, only possible in non-fiery mines, and even then not particularly safe. The use of a bare conductor, such as a trolley wire must be, does not altogether commend itself in collieries, unless there is absolutely no risk of the surrounding atmosphere becoming fiery with gas or dust. At the present time, it is true, there

Digitized by Google

are two such trolley wires in use in collieries in this country; but these are erected only in the main tunnels, near to the ventilating shaft, and at a safe distance from actual workings of the coal seams.

NOBODY but an American would have had the audacity to question the existence of the inventive faculty, and at the same time suggest that the education of human beings should from the entrance to the kindergarten to the exit from the University, be persistently directed towards its cultivation. This, however, it seems to us, is very much what Mr. W. H. SMYTH does in his interesting disquisition which we reprint in the present issue. He argues at great length that the inventive *faculty* is a myth, but insists to the end that "the first and most important prerequisite to invention is an absolutely clear insight into, and a comprehensive grasp of, all the conditions involved in the problem." The theory that the power of inventing is not strictly speaking a faculty like the power of perpetrating poetry, may be the correct one, and inasmuch as accuracy of thought, even in small matters, is a gain, Mr. SMYTH's theory may be an advance. Practically, however, it does not carry us very much ahead, since, humanly speaking, no amount of training will endow some minds with "the first and most important prerequisite to invention," whilst other minds, with next to no training, possess this great prerequisite in a high degree. In spite of the new theory, we are left, therefore, very much where we were before, and shall have to depend in future as in the past for the major portion of our new mechanical devices upon the "rare-brains" with a bent for inventing. To train everyone according to Mr. SMYTH's plan would doubtless have some marked result, but we may safely predict not the one he anticipates; no pedantic scheme of the kind indicated ever does yield exactly the fruit the prophet foretells.

WE have been compelled to hold over until our next issue several additional letters dealing with the magnetic unit question.

Cable Interruption :—

	Date of Interruption.
Cadiz—Teneriffe	Sept. 25.

Obituary.—The death is announced in the German technical papers of Herr Eugen Langen, part proprietor of the well-known cable works of Felten and Guilleaume, of Mülheim-on-Rhine, and inventor of the aerial railway system named after him.

Thermo-Dynamics.—Prof. Perry will deliver a special course of four lectures on "The Principles of Thermo-Dynamics and their Application in Engineering" on alternate Thursday evenings at Finsbury Technical College. The opening lecture will be delivered on the 24th inst. Further particulars appear in our advertisement columns.

Electric Lamps in London Tramcars.—Several of the cars on the Aldgate and Stratford line of the North Metropolitan Tramways Company have recently been fitted with electric light. The number of cars belonging to the South London Tramways Company, thus lit, is gradually increasing; and these cars are much more popular after dark than the dingy oil-lighted cars.

The Niagara-Buffalo Franchise—Latest.—The Niagara Falls Power Company and the Buffalo City Council have now, says the *Electrical Engineer* of New York, so far reconciled their differences as to the proposed franchise that terms have been agreed upon, and a franchise will at once be granted. In the main, the reasonable requests of the Company have been granted, and there is now every reason to believe that Niagara power will be delivered in Buffalo during 1896.

The Institution of Junior Engineers.—The annual general meeting of this Institution was held on Friday, October 4th, at the Westminster Palace Hotel, the retiring Chairman (Mr. H. J. Young) taking the chair. The principal business was the presentation of the Council's report on the proceedings of the past year, and the election of officers for the ensuing session. The report showed that steady advancement had been maintained. The membership roll had increased by 45, the total at the present time being 418. Mr. H. J. Young was re-elected Chairman.

An Agricultural and Mineral Light Railway in Missouri.—According to the *Western Electrician* of Chicago, a cross-country electric railroad has just been completed between Carthage and Carterville in Missouri. The distance is 15 miles. Carthage and Carterville are in the centre of the rich lead and zinc-producing section of Missouri, and a great deal of mining machinery is scattered along the line of the road. If the line proves a success it will be extended to Kansas City, 10 miles farther. The projectors propose to try in a limited way to furnish power to a mill on the line, and also to experiment in lighting farmhouses. The subject of furnishing power to threshing machines will be considered next year.

Thomson-Houston Tramway System in Europe.—Statistics published by the Union Elektricitäts Gesellschaft of Berlin, show that on May 1st last there were working in Europe on the Thomson-Houston system 14 tramways, with a total length of line of 105 miles and 381 motor cars. There were further in course of erection and preparation 142 miles of lines with 644 motor cars. Germany has five lines in operation, viz.: Bremen, Remscheid, Hamburg, Gotha and Erfurt, with nine lines in progress. The first tramway on the Thomson-Houston system was run in 1887, and to-day there are 450 lines worked on this system, representing a total length of about 9,000 miles, with 7,000 motor cars.

Electricity in Blast-Furnace Plant in America.—According to the *Railway Review* of Chicago the Carnegie Company will shortly erect six blast furnaces close to their steel works at Duquesne, Pa. The furnaces will be the largest ever built and the whole plant equipped with the best apparatus in such a manner that most of the work will be done automatically by electric and steam power. When completed the electric power station will generate about 3,000 H.P. for light and power. There will be about 30 electric cranes, three or more electric travellers of 250ft. span, about 15 electric motor cars, half-a-dozen electric conveyors and a large number of stationary motors for driving miscellaneous apparatus. There will not be a single belt in the whole power station, as the generators will be direct-connected to the steam engines, and the arc machines direct-connected to the electric motors. In all the Carnegie Works electricity is used as much as possible, and with great success, especially at their Homestead Steel Works and their works at Bessemer. In Homestead alone are running electric motors aggregating 4,000 H.P., and in Bessemer about 2,000 H.P.

The Schuckert Projector.—Mr. W. H. Pretty writes us as follows :—

It was with deep regret that I read the announcement of Herr Schuckert's death in your columns, and many who have worked his projectors after working other types will long regard him as a benefactor. It is necessary to know the difference by actual working to fully appreciate his improvements. The workmanship of the Schuckert projector left little to be desired, and, perhaps, for really rough weather and general outdoor exposure it was finished too well. It was about six years ago that I first saw and worked one of these large projectors, after several nights' suffering, caused by working other projectors, with which dark glasses were used for viewing the arc, and in which the adjustments had to be made by hand, without the refinement of a fine adjustment. The dark glasses or spectacles were not sufficient to protect the eyes satisfactorily, and often made it impossible to shut them or read with comfort for a day or two. I have also recollections of drops of molten copper from the negative carbon (which was coppered) finding their way to my wrist. I have no doubt there are many besides myself who will recollect the pleasure of working a large projector by Schuckert after such an experience as that

Digitized by Google

just mentioned. There was, with Schuckert apparatus, a plan and side elevation of the arc focussed on ground-glass surfaces, and the inequalities in burning would be readily adjusted without getting the hands burnt or the eyes hurt. The solenoidal control for the arc was very good, and the arc required little attention.

The Telegraph Service.—Mr. J. E. Naylor, Assistant Superintending Engineer of the Postal Telegraph Department, has just retired, owing to failing health, from the active service of the General Post Office. Mr. Naylor has been associated with the telegraph for a period of 40 years. Joining the British Telegraph Company in 1855, Mr. Naylor was appointed clerk-in-charge of that Company's office at Wakefield in 1860, and five years later he was promoted to a similar position at Sheffield. In 1868 Mr. Naylor became an inspector of the Engineering Department, and had charge of all the Magnetic Telegraph Company's wires and apparatus upon the Lancashire and Yorkshire Railway, from Sowerby Bridge to Goole and Leeds, and also upon the South Yorkshire Railway from Barnsley to Sheffield and Doncaster. On the taansfer of the telegraphs to the State he was appointed to the York district, and carried out the extensive erections of new lines that were then made from Beverley to Scarborough and Whitby, and from Leeds to Harrogate and Northallerton. On the rearrangement of districts that took place in 1878, Mr. Naylor was appointed to Leeds, where he carried out extensions and additions rendered necessary by the adoption of the sixpenny rate for telegrams. More recently he has taken an active part in the erection of the new trunk telephone lines that have been erected by the Post Office.

Bitumen Insulated Cables.—An interesting patent expires to-day; it is that granted 14 years ago to Mr. William Ormiston Callender, and numbered 4,409. Its title is "IMPROVEMENTS IN THE MANUFACTURE OF TELEGRAPH CONDUCTORS AND MATERIALS FOR COVERING AND INSULATING WIRE OR OTHER CONDUCTORS USED FOR TELEGRAPHIC, ELECTRIC OR OTHER SIMILAR PURPOSES." The invention consisted in the use of bitumen, combined with other hydro-carbons or their equivalents, in such a manner as to produce a compound suitable for insulating electric conductors, being "at the same time very efficient and inexpensive as compared with insulating materials ordinarily used." Trinidad bitumen is used, and the mode of manufacture is as follows: Thirty-five parts of bitumen and (in a separate cauldron) 35 parts of oil residue are melted, in each case three to four parts of vegetable oil being added. When thoroughly dissolved the two liquids are mixed at a temperature of about 220°F to 250°F. At this point about three parts of ozokerit or other equivalent wax may be added. The temperature is then raised to 280°F. to 290°F., and when the material is required (as is generally the case) to be vulcanised, about three or four parts of flowers of sulphur, or the equivalent thereof, are added, and the heat being raised to about 340°F., the mixture is stirred gently for about 45min., when it is brought into a thick elastic condition. It is kept for about two hours at the above temperature, and the result is the compound material found suitable for the purpose indicated. The claims are as follows: (1) The manufacture of the compound material produced by combining the natural deposits of bitumen with the oil residue or its equivalent, substantially as above described, whether the compound be vulcanised in the usual way or used without being vulcanised. (2) The manufacture of insulated conductors for telegraphic or other purposes by covering or coating the conducting wires with the compound prepared and vulcanised, substantially as above described.

An Electric Fire.—The following paragraph appeared in the *Standard* of Monday:—

A fire broke out early yesterday morning at 91, Onslow-gardens, South Kensington, a private residence in the occupation of Mr. A. Hughes. A man passing the house noticed flames issuing from a grating close to the pavement. On an examination being made of the vault under the roadway it was discovered that an electric transformer had caught fire. The flames were speedily extinguished, but the electric apparatus was completely destroyed.

Acting on the well-tried principle that the daily Press may always in matters of this kind be trusted to exaggerate and misstate, we made inquiries of the Company concerned, and received the following reply:—

DEAR SIR: Replying to yours of yesterday's date, the report referred to is, as usual, a gross exaggeration. The facts are these: Owing to the abnormal rains, water obtained access to the converter house, causing the fuses to be blown; but prior to this taking place the secondary of the transformer had commenced to smoulder. No flames whatever were seen, and no serious damage whatever done, as the transformer is fixed in a chamber built of brick, and this is in an out-house. The report contained in one or two papers is most certainly untrue, for the smoke issuing from the ventilating holes in the converter house was first seen by the servant, who informed the tenant, and he at once communicated with the local fireman instead of advising the Company, the result being that far more damage was very soon done and more smoke caused with the water which they poured on to the converter house by means of a hand pump than would ever have taken place if it had been left alone. This was due to the water being poured on to the high-tension fuses. In fact, the whole cellar was so badly flooded that our engineer could not obtain access for some considerable time, when, after the water was baled out, everything was made satisfactory and a new transformer fixed. We may mention that we have written to the tenant asking him that should such a circumstance take place again at his house we should be glad if he would please inform the Company before sending for the firemen, which only causes a good deal of alarm, and gives a very erroneous impression when such statements appear in the daily Press. We shall certainly be very pleased if you will kindly contradict the report.—Yours, &c.,

HENRY W. BOWDEN, Manager and Engineer,
The House-to-House Electric Light Supply Company (Limited).

Current Electrical Science.—Among the electrical monthlies *Wiedemann's Annalen* again bears the palm for the interest attached to its contents. No. 9 contains two entirely new and original devices for exorcising that evil genius of the advanced electrician—GROUND VIBRATION. Prof. Einthoven, of Leyden, supports his capillary electrometer on an iron slab weighing some 3cwt., and floating on a film of mercury 1mm. thick, and with excellent results. H. Julius suspends a small table by three long vertical wires attached to the vertices of an equilateral triangle. On this table he places his hypersensitive instrument, taking care to lower the centre of gravity by an adjustable weight under the table, and then he defies the earth tremor and the rumbling vehicle. H. Rubens adds to his spectroscopic and bolometric laurels by describing a VIBRATION GALVANOMETER for measuring alternate currents, which is claimed to be more sensitive than the electro-dynamometer and the thermo-voltameter, and more adjustable and useful than Wien's optical telephone. It is based upon the latter. An armature of soft iron wires is attached to a stretched wire, and is set into torsional vibration by an alternate current traversing four tungsten electro-magnets suitably arranged. The amplitude of the vibration is a maximum when its period is the same as that of the current, and this maximum is proportional to the strength of the current. It is attained by altering the length or the tension of the wire. A bright slit viewed in a small mirror attached to the wire appears as a luminous rectangle, whose breadth measures the amplitude. Peter Lebedew takes another step in the direction of using optical apparatus for ELECTROMAGNETIC WAVES. As a resonator he uses a small thermo-couple. Polarisation, interference, rectilinear propagation, reflection, and refraction of electromagnetic waves are all shown by instruments a few centimetres in size. A small prism of ebonite 1·8cm. high, serves to determine the refractive index, which figures at 1·6. Double refraction is exhibited and measured in a prism of rhombic sulphur rubbed (not cut) into its proper shape, and a quasi-nicol prism is constructed of two sulphur prisms with a plate of ebonite between them! We need only glance at a further Paper by E. Wiedemann and G. C. Schmidt, "On the Cathode Luminescence of Organic Bodies," and at R. Reiff's mathematical disquisition upon the laws of electric motion in metals and electrolytes, to appreciate the *embarras de richesse* in German electrical science.——When our Italian friends have had enough, for a time, of seismometers and transcendental geometry, they sometimes come out with a striking electrical novelty, such as electrostatic hysteresis. The recent numbers of the *Rendiconti dei Lincei* do not, however, show such a reawakening, and we only find Prof. Cattaneo in the August number struggling to unravel the intricacies of ELECTROLYTIC CONDUCTIVITY—a field which needs unselfish workers.——The *Journal de Physique* for September contains an investigation by Pierre Weiss on the comparison of mutual inductions by the BALLISTIC GALVANOMETER. When the two opposite impulses are not given at exactly the same instant they must at least be infinitely near in order to measure their difference to within an infinitesimal of the second order. Well, it might be worse.

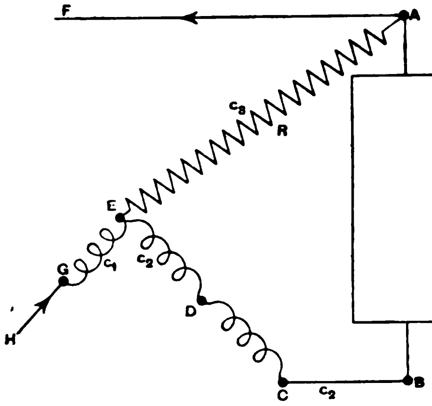
AN ALTERNATING CURRENT WATT-METER.

BY PROF. JOHN PERRY, F.R.S.

About two years ago I invented a very simple instrument, which measures watts exactly, however great the lag may be in amperes behind volts. Only one reading is necessary, and the instrument costs about the same as a Siemens dynamometer. I have had only one specimen made, and I have made no efforts to get it manufactured because I have found that in nearly all practical work the error when one uses an ordinary dynamometer is quite negligible. This is due to the fact that sufficient power is wasted even in an unloaded transformer in eddy currents and hysteresis to prevent the lag being excessive. But it may be that in the future greater exactness may be wanted, and it may be well to describe my instrument. I had intended to publish a number of tests made by Mr. Eborall, late of the Finsbury Technical College, but as they only bear out what anyone can see to be true from the construction of the instrument I need not trouble the reader with them. Mr. Eborall constructed the instrument which he tested.

In the figure, A B is any contrivance to which electric power is being given by alternating currents; it may contain motors, condensers, choking coils, lamps or other apparatus. There are two coils of wire, E G and E D, which are wound together on the fixed bobbin of a dynamometer in such a way that if the same current passes from G to E and E to D no magnetic effects will be produced; in fact, the fixed bobbin is differentially wound. The coil D C is the movable coil of the dynamometer.



It is therefore evident that the reading of the instrument represents (to some scale dependent on number of turns of wire and the controlling moment) the average value of $(c_1 - c_2)\, c_2$ or $c_3 c_2$. Now, E A is a non-inductive resistance of amount R, and if this is known, since $R c_3$ represents the voltage between E and A, the reading of the instrument represents the average power supplied to A B and to the part E B. The power supplied to the part E B is insignificant. The instrument is easily graduated and tested by continuous currents. Also at any time, by disconnecting E A, we can test whether G E and E D completely destroy each other's effects on the movable coil, and if they do not do so it will usually be found that a slight adjustment in position of one of the wires to the binding screws G or D will be a sufficient correction.

Even if the small power supplied, say, to an unloaded transformer is to be measured, and if the ordinary Siemens dynamometer frame and method of control be employed, I have found that the cost of and space taken up by the non-inductive resistance are not of importance. Of course, they are of less and less importance as the power is greater, and as the volts are less and if a more delicate method of control is employed. Anyone who cares to employ this method will find it well to remember that if he uses considerable resistance between E and A, or if from any other cause the currents c_1 and c_2 are considerable and their difference small, it will depend upon the nature of the control whether there may not be too much heating of the fixed coil for its structural safety when measuring up to the limiting readings of the instrument.

In this description the words fixed and moveable are interchangeable. The method is applicable to motor supply meters.

NOTE ON SOME MANGANIN RESISTANCE COILS.

BY E. O. WALKER.

Dr. Alex. Muirhead has in his laboratory two B. A. units constructed of the manganin of Dr. Lindek, the constituents of which are copper 73 per cent., nickel 3 per cent., and manganese 24 per cent. The wire of which the coils is composed has not been annealed, and is covered with silk and shellac. So far as observations have been taken the coils seem to increase in resistance with temperature, and *vice versâ*, and do not therefure acquire, at a critical temperature, say 16°C., as some experimenters have found, a negative temperature coefficient above, and a positive coefficient below, that temperature.

The material has, as is well known, a remarkably low temperature coefficient, and if this remains constant throughout a range on the thermometrical scale, say from 0deg. to 30°C., without change of sign, manganin may yet prove to be a valuable standard of reference. Coil No. 1 is certified at the Cavendish Laboratory to have a value of 0·99996 B. A. unit at 13·7°C. It was tested against a Matthiessen B. A. unit, No. 78, of platinum-silver alloy, which was kept at as constant a temperature as possible, while that of the manganin was varied. No. 78 was immersed in a jar of water enveloped with a double wrapping of thick flannel. The manganin coil was in a double tin, two water spaces and a wrapping of cotton wool separating it from the air of the room; a glass tube connected with a reservoir permitted water to drop into the outer tin, and an escape pipe drew off the overflow. By this means temperatures up to 33°C. could be maintained constant for half an hour even in cold weather. It was found that this period was essential to permit of the innermost parts of the coil assuming the same temperature as that of external parts, and of the case and air space surrounding it. The comparison standard, No. 78, varied in temperature during the tests (which occupied some hours) only from 14°C. to 17·4°C., and allowance for a corresponding change in its resistance, using a temperature coefficient of 0·00025 (or percentage variation per degree C. of ·025), was made in the calculations applied to find that of the manganin No. 1 coil. The temperature coefficient in question is that found by actual test for coil No. 78, between 14°C. and 33°C.

Manganin coil No. 1 was raised in temperature from 14°C. to 25°C. in warm water, and by the means above indicated. Tested on the bridge against No. 78, it showed an increase in resistance equivalent to an average temperature coefficient of 0·000011, or percentage variation per degree C. of 0·0011.

Manganin coil No. 2 was then compared with manganin coil No. 1. When both were at 12·6°C. No. 2 was found to be 0·036 per cent. higher in resistance than No. 1. When No. 2 was in melting ice, and at a temperature of 0·3°C., and No. 1 was at 12·5°C., the temperature of the room, then No. 2 was found to be 0·013 per cent. less than No. 1. This would give a temperature coefficient of 0·00004 per degree from 0·3°C. to 12·6°C. for No. 2 coil. It is evident that this alloy, or these particular coils made from this alloy, does not at low temperatures behave differently from other known alloys. While No. 1 was kept at a temperature of 14·2°C., No. 2 was now heated to 32°C. The latter was now found to be 0·046 per cent. greater than No. 1, and shows a calculated temperature coefficient of 0·000006, from 12·6° to 32°C.

These coils seem, therefore, to have properties different from most others of manganin, and if they can be imitated, some valuable units may be made available.

All the necessary tests were made by the aid and with the resources of Dr. A. Muirhead.

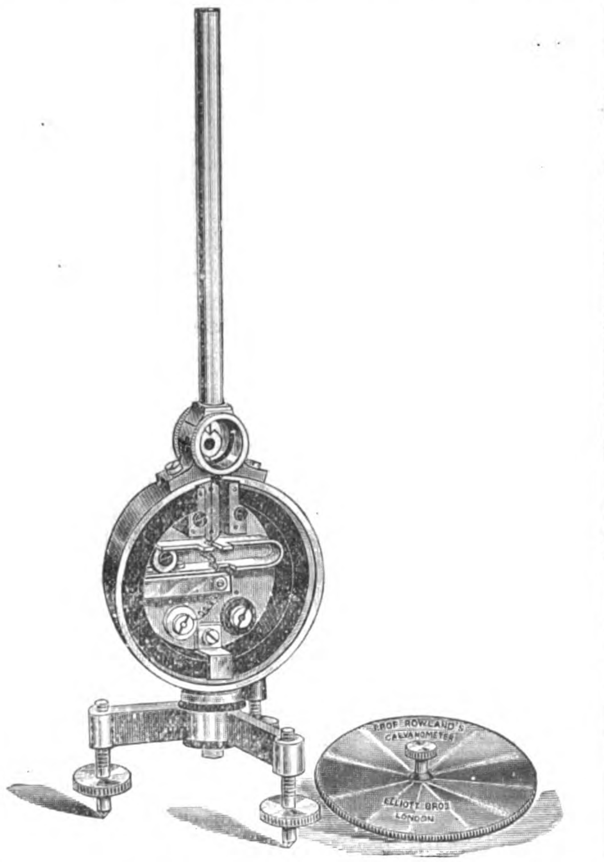
THE ROWLAND REFLECTING GALVANOMETER.

In a great number of cases at the present day, where accurate measurements of resistance and tests of insulation by direct deflection are required, the small space available in electric light engine rooms and power stations renders the employment of an ordinary pattern of reflecting galvanometer

Digitized by Google

almost useless, on account of the strong magnetic fields in which testing instruments are now required to work. These conditions have tended to develop to a high degree of perfection galvanometers of the d'Arsonval type. The accompanying illustration shows one of the latest instruments of this type the various features in which are the result of a great amount of experiment and practice by Prof. Henry Rowland, of America, and from his experiments and designs the instrument has been put into practical shape by Messrs. Elliott Bros.

One of the chief points which has been borne in mind in the design of this instrument is that the suspension should be easily got out for renewal. In many galvanometers nowadays the renewing of the suspension involves a considerable amount of work, and requires experience, in order that the galvanometer shall keep its zero. In the instrument under notice these difficulties are, it is claimed, almost entirely overcome. By removing the covering tube at the top of the instrument, a portion of the tube which carries the top end of the suspension is entirely cut away in the front, so that the suspension pin at



the top of the instrument can be lifted right out; the suspension, mirror, coil, &c., passing through a vertical slot, which is continued right down through the front of the instrument.

Another point worthy of notice is, that the suspension is fixed to the stem passing through the coil, and the suspension pin at the top. By means of specially designed spring hooks at each end of the suspension, which is of special metal to ensure reliable deflections and permanent zero, two small links are fixed by a method which does not require any heating of the suspension strip. These suspensions are all made of an exact length, and can be had of various strengths. The links are hooked on to the small hooks on the coil stem, and the suspension pin at the top, thus making the replacing of a broken suspension a matter only of a few seconds. To ensure good contact between these hooks and the suspension they are all gilded, and are thus found to give a very satisfactory and permanent means of ensuring good connection.

The instrument, which in itself occupies a very little space, is mounted on a small tripod frame, and is movable about on a vertical axis, so that the light spot can very readily be set round to any desired position. The suspended system can very readily be raised when the instrument is carried from place to place. These advantages, combined with the high grade of sensibility of the instrument, should make the instrument one specially suitable as a practical galvanometer for the use of central station engineers.

CONVERSION TABLE FOR "RATIONAL" UNITS AND PRESENT UNITS.

In our leading article on "Magnetic Units" on the 13th ult. we gave, on what we believed to be good authority, the value of a conversion factor between Mr. Heaviside's unit of magnetism and the corresponding unit at present in use. In our report of the discussion which took place at the British Association on the proposed magnetic units, an equally good authority gave the reciprocal of the former number as the value of the conversion factor. We can only attribute this to the persistent and inherent property of 4π of turning things upside down. In order to remove any misconception which may have arisen, and to prevent confusion for the future, we have compiled the following Table of conversion factors, which we have every reason to believe correct:—

1	"rational"	unit of magnetism	= 0·28205	of present	unit of magnetism.
1	"	unit magnetic field	= 3·5441	"	unit magnetic field.
1	"	magnetic line	= 3·5441	"	magnetic line.
1	"	unit of magnetic potential	= 3·5441	"	unit of magnetic potential.
1	"	ampere	= 2·8205	"	amperes.
1	"	volt	= 3·5441	"	volts.
1	"	ohm	= 1·2566	"	ohms.
1	"	henry (or secohm)	= 1·2566	"	henrys (or secohms).
1	"	ampere-turn	= 2·8205	"	ampere-turns.
1	"	ampere-turn	= 3·5441	"	gauss.
1	"	coulomb	= 2·8205	"	coulombs.
1	"	farad	= 0·79577	"	farads.
1	"	watt	= 10	"	watts.
1	"	joule	= 10	"	joules.

It may also be pointed out that 1 "rational ampere-turn" = 1 "rational gauss"; and that in passing from the rational absolute system to the rational practical system only *one multiplier* (or divisor), viz., 10^8, is employed.

THE PROPAGATION OF THE MAGNETISATION OF IRON.*

BY W. PEUKERT.

When a long straight iron bar is excited by a magnetising coil situated at the centre, the lines of force, all of which pass through the coil, do not keep in the iron up to its extreme end, but emerge into the air at all points along its length, so that the induction in the bar falls off continuously as the distance from the central source of magnetisation is increased. With a periodically varying magnetising force the same effect is produced, and, moreover, the corresponding periodic changes in the induction induce eddy currents in the iron. These cause a lag in the phase of the induction which increases as the end of the bar is approached.

Experimental proof of this was carried out on rods of about one metre length of wrought and cast-iron, and on a large bundle of soft iron wires of 1mm. diameter. The induction at various points was measured by search coils placed at intervals on the bar, and readings of the instantaneous values of the induction were taken through a complete period for each coil. The readings were obtained by means of a contact-maker fixed on the alternating-current dynamo used for exciting the magnetising coil, the momentary currents being indicated by a Wiedemann galvanometer. Magnetomotive forces of 288 and 1,306 ampere-turns were used. The curves of induced E.M.F. obtained from all three samples show a shift of phase which increases with the distance of the search coil from the centre of the bar, both at the lower and at the higher values of the induction. The curves are not symmetrical with the zero axis, the difference being attributed to residual magnetism. There is no marked difference between the changes of phase produced in the solid and in the laminated specimens, the amount of shift not being sufficiently clearly defined to show any distinct difference. The magnitude of the deflections continuously falls off along the bar, showing the diminution in the induction.

THE LA GOULE POWER TRANSMISSION PLANT.*

The La Goule transmission plant is at the present time one of the largest of its kind in Switzerland, and supplies current to 11 villages of the Bernese Jura district, which are situated up to 15 miles from the generating station. As motive power the water of the Doubs near La Goule is used, there being a minimum supply of 530 cubic ft. per second at a fall of 85ft., which represents a total capacity of 4,000 H.P. A canal, consisting of a tunnel, an open way, and wrought-iron pipes, conveys the water to the power house about 700 yards distant. Here provision is made for the utilisation of 2,000 H.P. At present there are erected three horizontal Girard turbines of 500 H.P. each, running at 200 revolutions per minute, and coupled direct to three Oerlikon alternators. The turbines are of Escher, Wyss and Co.'s make, and fitted with automatic regulating apparatus. This is driven by belt off a horizontal shaft, which receives its motion from the vertical turbine shaft by means of bevel wheels, &c., which also drive the exciter. To prevent the water in the main pipes freezing, a special valve is placed between the second and third turbine to permit of an artificial circulation being created in the mains when the turbines are stopped. The ordinary alternating current is employed at 5,500 volts. The reason for this was mainly to simplify the working of the plant, as the current supplied was used for power and lighting purposes. The principal business of the district is watchmaking, and therefore a large number of motors will be connected up in time, besides the extensive lighting installations, which will be erected in the different workshops. For lighting, the single-phase alternating-current system was thought the most suitable, and to ensure unity in generation the same was also adopted for the power section. There are, however, two separate sets of conductors—one for lighting and one for power, but all generators feed on to the same switchboard.

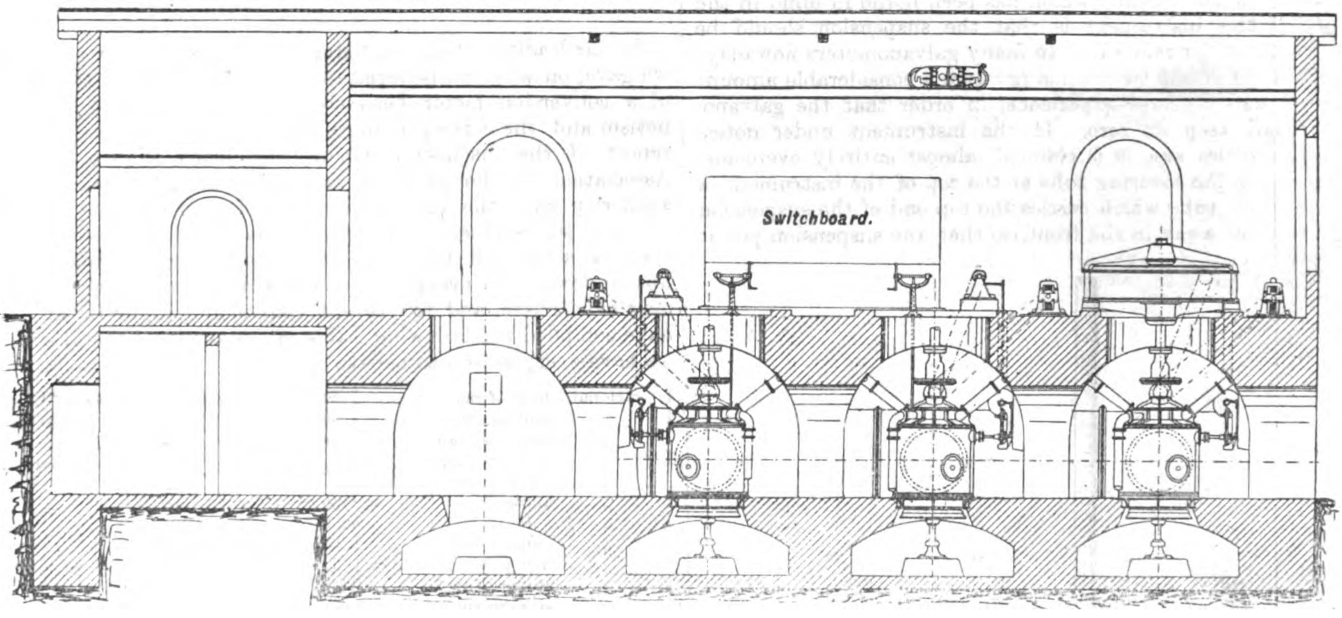

Fig. 1.—Sectional Elevation of Power House.

Figs. 1, 2, and 3 show the general arrangement of the station. The alternators, of the Oerlikon horizontal type, with revolving fields, are placed direct over the turbines. At 200 revolutions, and with 500 H.P. absorbed, the output of each machine is 63 amperes at 5,500 volts, which is equivalent to an efficiency of 94 per cent. The periodicity is 50 per second. The stationary armature, which is insulated from the bed-plate of the machine, is of the channel type, and contains 30 coils, pressed in to the projecting teeth. The field is excited by one large coil, receiving its current through two collecting rings. The excitation of each alternator requires 2,400 watts, or about $\frac{3}{4}$ per cent. of the capacity of the machine. The field ring is 8ft. 3in. in diameter, and weighs nearly 10 tons. The armature with the two bearings weighs $12\frac{1}{2}$ tons. The exciters are ordinary two-pole machines, having an output of 30 amperes and 80 volts when running at 700 revolutions, and are driven by belt, as described above. The connecting conductors between generators and switchboard are carried through a subway. The switchboard is of black marble, and arranged in three sections. Power and lighting circuits occupy the two outside sections, and dynamo and exciter instruments and switches the centre one. All the outgoing circuits are provided with lightning arresters. The high-pressure mains have an extent of 22·4 miles, with a total length of 186 miles of bare copper wire, having a total weight of about 77 tons. There are three complete high-pressure ring mains for power and lighting.

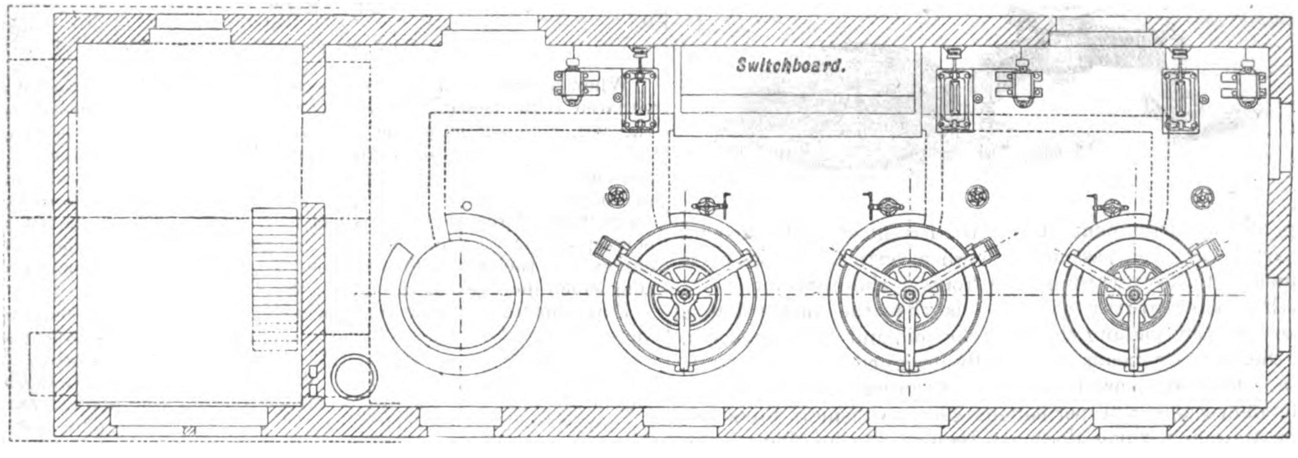

Fig. 2.—Plan of Power House.

The general positions of the different villages is shown in Fig. 4. The conductors range in diameters from 2·5mm. to 7·5mm., and are

* From the *Elektrotechnische Zeitschrift.*

Digitized by Google

carried on porcelain insulators fixed to wooden poles. Eighteen wires leave the power house, and run as far as Noirmont. This represents about 5cwt. of copper between two poles. The fall of potential in the primary mains attains a maximum of 10 per cent. for lighting and 20 per cent. for power.

In each village there is one transformer sub-station a small brick building, fairly centrally situated. Two separate circuits are provided for the distribution, one for lighting and one for power. Distribution is carried out on the three-wire system, and, like the high-pressure circuits, the distributors are mostly overhead. Telephones connect all the sub-stations with the power house and the offices at St. Imier.

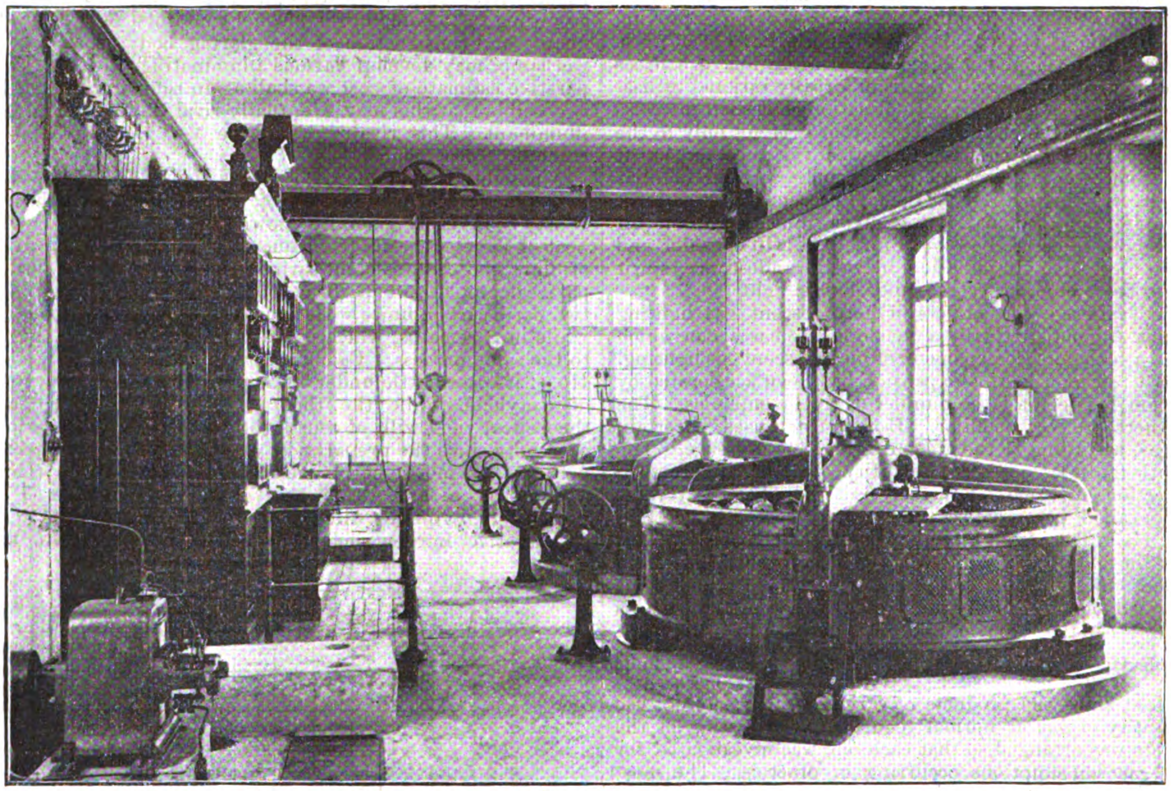

FIG. 3.—General View of Power House.

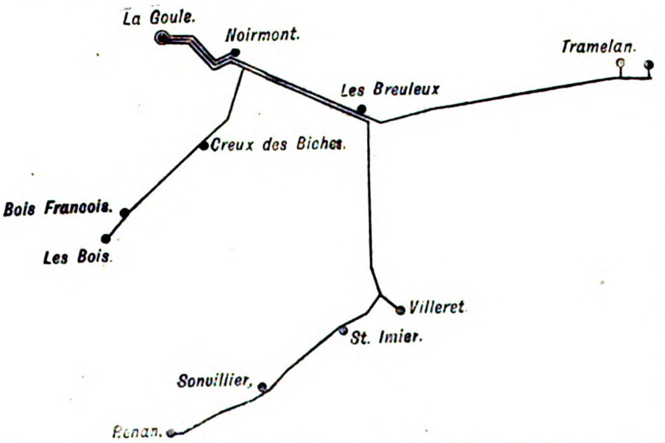

FIG. 4.—Sketch Map showing relative positions of villages among which power is distributed.

The motors used in the district are of the Oerlikon single-phase alternating current type, with special starting apparatus in which the middle wire of the three-wire system is made use of.

It is generally thought that this kind of motor starts rather badly, even at a very light load, and the Oerlikon Company has overcome this difficulty by providing an extra loose pulley on the motor, allowing it to start with no load whatever. The act of starting is as follows: The belt rests on the loose pulley, the motor is started up, and when running at its normal speed the loose pulley is pressed against the fast one of the motor by means of a friction arrangement. As soon as the belt is running at the proper speed it is shifted on to the fast pulley by means of an ordinary striking gear, and the loose pulley is then disengaged. In Fig. 5 the connections of the motor to the secondary three-wire system is shown. The handle H of the throw-over switch, which is in the middle position when the motor stops, is brought into the position L. Two copper bars, insulated from each other, fixed to the switch handle, connect the three contacts on the left of the handle, and also the two contacts on the right of the same; and, as will be seen from the diagram, the starting current is taken from the middle wire and one of the outside ones, the main coil of the motor being connected to terminals 1 and 2, and the starting coil to 2 and 3. When the armature has run up to its normal speed, taking about ½min., the

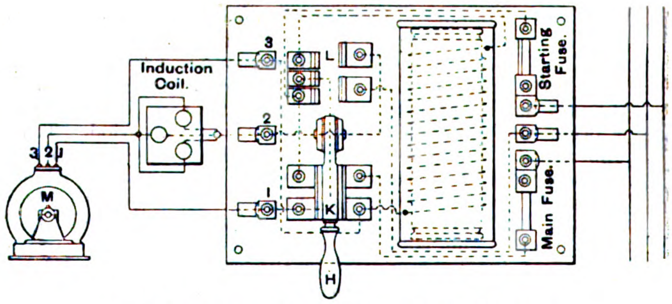

FIG. 5.—Diagram of Connections for Starting Motor.

switch handle is thrown into the position K, and then left there during the time the motor is working. As will be seen from the diagram, the current is then taken from the outside mains of the three-wire system. The middle wire is therefore only used for starting the motor, as mentioned before. If an induction coil is inserted in conductor 2 of the motor, the iron core of the same must be pushed right in before the switch handle is brought into position L, and then drawn gradually as the motor starts running.

The plant runs continuously with only a stoppage of half an hour at noon every day. Current is supplied to private customers for lighting purposes at 1s. 2d. per candle-power per year; for power purposes at £13 per horse-power per year for motors from 2 H.P. to 12 H.P. For larger motors special terms are made.

COMPARATIVE STUDIES OF ACETYLENE GAS LIGHT AND THE ELECTRIC ARC.*

BY W. WEDDING.

Owing to the vast development of electrical engineering during the last 10 or 20 years the whole subject of illumination has undergone a great and progressive change. Not only is the use of electric arc and glow lamps extending, and their working improving every day, but on the other side also great efforts have been made towards the further development and greater utilisation of sources of light. In practice we are still far from a really rational utilisation of energy for the purposes of illumination, but such progress has been recently made in this direction that it is not only to the general interest to consider the present state of the question, but it is important that every electrician should make himself familiar with this progress. On the basis of the more recent investigations, for which ample numerical material is given in the *Journal für Gasbeleuchtung und Wasserversorgung* (Bunte), we will consider and compare the progress in illumination by gas incandescence, spirit incandescence, petroleum, acetylene, and electric light.

About eight years ago the success of incandescent gas lighting was very doubtful; but gradually a development has set in which has now led to a considerable expansion of incandescent gas lighting. During the last few months this expansion has been accelerated by the competition between a large number of rival companies. The types of burners are very similar. Each burner uses a certain quantity of gas, according to the apertures and the pressure. The glowing mantle radiates a certain quantity of light, different in different directions in space. For each unit of light (the Hefner light, shortly called one candle) the burner consumes a certain quantity of gas. The quantity of gas necessary to sustain one candle-power for one hour we will call the effective consumption. For the Auer incandescent gas light (German Incandescent Gas Company) an hourly consumption of 1·38 cubic ft. of gas is reckoned for a candle-power of 60 in a horizontal direction. Hence the effective consumption is $\frac{1\cdot38}{60}=0\cdot023$ cubic ft. per hour for 1 c.p. Now, since the products of various factories do not use the same quantity of gas at normal regulation, the testing of the various burners was arranged so that each one was investigated for the different gas consumptions occurring in practice. The most favourable—*i.e.*, the lowest effective consumption—was taken as characteristic for the burner, and the test of efficiency was only applied at this rate of consumption and at this pressure. The value above given for the Auer gas burner was verified, but the candle-power sometimes falls to 40 or rises as high as 90.

Tests made at Christmas last year showed that competitors were still far behind the efficiency of the Auer lamp. In general the initial lighting power was 20 c.p. to 30 c.p., and the effective consumption two or three times that of the Auer. But the initial consumption is not decisive. The total consumption over a longer period is what is practically important. On burning the lamps for 230 hours it was found that the effective consumption exceeded 0·07, while the Auer mantle did not reach 0·03. But although these first competitors must be considered failures, there soon was a change. This was first observed in the so-called diamond light, manufactured by Trendel. The effective consumption began under 0·024 in many cases, and only reached 0·037 after 200 hours. Those made by Butzke have shown an approximation to the Auer mantle to within 17 per cent. No lamp need be tested for a period exceeding 300 hours, since that is the normal life of a mantle. In some way or other the mantle is destroyed within that period. That with proper treatment the mantles may keep longer has been made evident by previous measurements. For six Auer burners, which up to the present have burnt 3,000 hours, the average result is that after the first 500 hours the candle-power falls to two-thirds, and after 2,000 hours to one-half of its initial value.

The colour of the light emitted by the different makes differs with the nature of the earths with which the mantles are impregnated. The Auer body has a slight green tinge. That of Kramme is very white, while Butzke's lamp is reddish. This is no doubt pleasanter for the eye, but if we bear in mind that the luminous effect of the different colours are—red 1, yellow 28,000, green 100,000, and violet 1,600, it is evident that the prevalence of green rays will give the greatest efficiency.

The incandescence of the earths used in incandescent lighting need not be produced by the high temperature of the Bunsen gas burner, but may also be brought about by using other gases or liquid hydro-carbons converted into gas. The method of illumination by spirit incandescent burners is based upon the latter principle. Imagine a common lamp filled with spirits instead of petroleum. Through a wick the liquid spirit is sucked up in a tube, and is heated to vaporisation by a small spirit flame attached to the side and fed from the same reservoir. The spirit vapour is conducted through the tube into the usual incandescent gas burner, which is screwed immediately on to the tube; and instead of the coal gas the spirit vapour is used to render the mantle incandescent. To ensure greater constancy in brightness when the lamp is moved, the tube containing the heated spirit vapour has recently been widened out into a little boiler, and the mantle is thus kept in a uniform state of incandescence, even when moving it about in the room. According to the amount of spirit vaporised, and especially according to the amount of alcohol contained in the liquid, and the quality and construction of the glaring body, such a lamp, like a gas lamp, may develop various illuminating powers. In the comparative estimate of cost we shall again refer to this new lamp. It is possible that this may eventually rival the petroleum lamp as an illuminant. This rivalry would be very important and of far-reaching consequence.

A possibly formidable rival to gas lighting has been born in the now practicable manufacture of acetylene from calcium carbide. It may be taken as generally known that by the influence of the great heat of the electric arc (continuous or alternating) upon a mixture of lime and coal, calcium carbide is generated, consisting of one part calcium to two parts carbon. On pouring water over this, two parts carbon unite with two parts hydrogen to form acetylene, while lime remains, which is again mixed with coal and subjected to the same process. Calcium carbide is commercially obtainable; 1lb. of it costs a little under 3d. at present, and gives out 0·6 cubic ft. of acetylene, while the theoretical yield is 2·1 cubic ft. The theoretical yield will, of course, be further approached in practice, especially since the preparation of almost pure calcium carbide (95 per cent. or more) has been accomplished. When there is production on a large scale also it is to be expected that the present high price will be reduced. Burnt in a two-hole regenerative burner such as is used for oil gas, the flame give

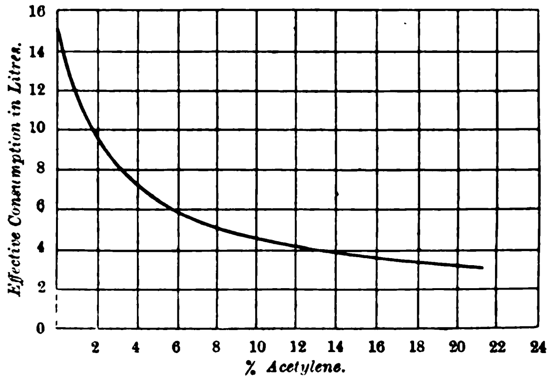

FIG. 1.—Effective Consumption with various percentages of Acetylene.

34 c.p., with an hourly consumption of 0·26 cubic ft. of acetylene. Hence the effective consumption is 0·077, and the amount of gas used is one-third of that for incandescent gas.

If acetylene is burnt with an open flame in a Bray burner, such as is usually used in street lamps, it is necessary to mix air with it artificially to prevent smoking, and to obtain a brilliant quiet flame. The best percentage for the mixture is 47 per cent. acetylene. With such a burner the candle-power was 52, and the effective consumption was 0·01 cubic ft. of acetylene per candle-hour. But since this mixture is very explosive we tried carbonic acid instead of air, which made the effective consumption half as high again; hence this experiment must be considered a failure. If acetylene is to be used for street illumination, the object must be to enrich the coal gas wherever that exists. In experimenting in this direction we obtained the curve shown in Fig. 1, which shows the effective consumption of gas in its dependence upon the percentage of acetylene in the mixture. Without acetylene the burner had an effective consumption of 15 litres (1 litre = 0·035 cubic ft.); with 6 per cent. acetylene it only required 6 litres of the mixture of coal gas and acetylene; at 12 per cent. the consumption fell to 4 litres, and at 21 per cent. to 3 litres.

We will now compare the cost of the most usual illuminants.

With the present prices of gas, coal, petroleum, methylated spirit, and calcium carbide in Berlin, the 16 c.p. lamp, according to the various systems, would cost per hour—

Incandescent gas	0·06d.
Incandescent spirit	0·144 to 0·3d.
Petroleum	0·24d.
Argand burner	0·30d.
Electric glow lamp	0·36d.

The Berlin prices assumed are: gas, 6s. per 1,000 cubic ft.; methylated spirit, 1s. 2d. to 2s. per gallon; petroleum, 1s. 4d. per gallon.

* Abstract of a lecture delivered before the third annual meeting of the Verband Deutscher Elektrotechniker, Munich.

Digitized by Google

As regards acetylene, its economy depends altogether upon the price of the acetylene which is to be mixed with the gas. Coal gas alone would require ½d. per hour for a 16 c.p. light, and an addition of acetylene up to 21 per cent. would steadily increase the price up to ¾d. If the price of acetylene falls, the cost of the light falls, especially with a *slight* admixture of acetylene. If the price of the cubic foot of acetylene should ever fall from the present figure of 5d. to ½d., the economy of the gas would increase with every addition of acetylene, although any additional admixture beyond 10 per cent. would have hardly any effect. If the acetylene is not burnt in the open, but in the regenerative burner, the price per 16 c.p. would be 0·6d.—*i.e.*, ten times as much as incandescent gas. Hence great reductions must yet take place before the latter can be competed with. We see, then, that the succession of economy is—incandescent gas, incandescent spirit, petroleum, argand burner, electric incandescent light, acetylene.

Above all these, as regards economy, stands the electric arc light. It is well known that the efficiency of the arc light is seven times that of the incandescent lamp. Hence the arc lamp costs only 0·06d. per 16 c.p. But the arc light has many advantages which make it in many ways unquestionably superior to all other illuminants. In the first place, the light is chiefly given out at an angle of 45deg. below the horizontal, which gives a uniform illumination, even at greater distances. In the incandescent gas light the maximum lies above the horizontal, and the shades applied hitherto have only succeeded in concentrating the light immediately below the lamp. For large spaces no light approaches the arc light. With gas we can approach 100 or 200 c.p., but not the thousands of the arc. Since arc lamps have been constructed for currents as low as 1 ampere and 40 watts, giving out 40 c.p., with a maximum of 65 c.p., such lamps have come into use for smaller requirements, and can be used unshaded, like incandescent gas. Another advantage of the arc is in its colour. Although it contains many violet rays the other radiations are present in such quantities that everything of a light colour appears light, whereas red objects appear dark by the somewhat greenish incandescent gas light. Although, therefore, the costs for arc light and incandescent gas are the same, still there are such essential and unattained advantages on the side of the arc light that the illumination of large areas by its means is distinctly the most advantageous.

IMPROVEMENTS IN ACCUMULATORS.

In a Paper read before the May meeting of the Electrotechnical Society at Cologne, Dr. E. Sieg described the new type of cell manufactured at the Cologne Accumulator Works, and gave an account of some exhaustive experiments which have been made on it. The difficulties connected with the casting of the Hagen lattice grid have been overcome by the use of an improved mould which allows of the easy withdrawal of the casting. Even with this improvement, it is not possible to cast grids having a less thickness than 4mm., so in the construction of the negative plates the firm employ the form patented by Herr Aloys Zettler, of Munich, which allows of a still thinner lattice. The need for portable accumulators constantly increases, and this has led the Company to pay special attention to this type, of which they now consider they have a very good practical form. The plates are kept apart by perforated, waved celluloid separators, which form of construction gives great resistance to lateral pressure, while allowing the electrolyte to circulate. The distance between the plates is reduced to 2½mm. to 3mm. The cells are formed of hardened lead, and are closed with soldered covers. These batteries are well adapted for traction and train-lighting purposes. The railway post-office carriages have accumulators of the Boese-Lütcke system; the Dortmund-Gronau Railway is lighted by accumulators from the Hagen factory; the Marienburg Railway uses the Cologne factory accumulators. Each carriage contains a battery of eight cells. Four wooden cases, each holding two cells with six positive and seven negative plates of 15cm. by 18cm., are connected, and put into a wooden case. Wooden ledges on the front and back of the case press against india-rubber bands, and prevent any movement of the cells. Their capacity is 108 ampere-hours, with 15 volts and 28 amperes maximum discharging current, the charging current being 18 amperes and the weight 170 kilogrammes. The high rate of charge which can be employed with the lattice grid is a special advantage, as the cells can be charged in six hours, whilst the post-office accumulators require 22 hours. The arrangements on the Marienburg Railway are interesting, as the accumulators not only serve for the lighting of the trains, but also for that of the platform, the first and last passenger carriages being provided with an arm at each side, by the laying out of which a 20 c.p. lamp is automatically switched on. The train is chiefly employed for goods traffic towards the Russian frontier. All unnecessary use of the light is avoided, as, besides the main switch to the carriages, each compartment has its own switch, which is not turned on by the guard until a passenger enters. For trains with small passenger traffic this arrangement seems practical, and the lighting of the carriages and stations is better and cheaper than it was under the old system with oil and candles.

The well-known belief that accumulators can be over discharged for a short time without injuring their durability was made the subject of very severe tests, full accounts of which are given. As the result of these experiments the author concludes that accumulators which are subjected to great strains should not be discharged beyond the guaranteed performance, which is about two-thirds of their capacity. With a very high rate of discharge an accumulator has not the same capacity as when it is discharged with a normal or weaker current; as with slow discharge more and more of the inside of the active material comes into use. As the result of these experiments the firm has no hesitation in allowing a short discharging at too high a rate, provided it does not affect the limit of discharge, as it is the too prolonged discharge which is especially injurious to accumulators, since it is the sulphating which then takes places which causes the buckling of the plates, especially when, as often occurs in private installations, the too long continued over discharge is not immediately followed by a charge.

These experiments were confirmed by those recently carried out in Carlsruhe. The General Committee of the Baden State Railways sent out a tender for the delivery of a battery for the electric crane in the Mannheim harbour, and on the strength of the offers of three firms, required cells capable of discharging at the rate of 1,000 amperes for the purposes of comparison. These experiments lasted over three months. As it was found that the discharge at two and three times the normal rate injured the cells so little that no definite opinion as to their relative merits could be formed, the current strength was gradually increased to 5,300 amperes, when a further increase was rendered impossible by the failure of the provisional connections with the measuring instruments. The cells were further discharged with a strong current, and left two days and nights short-circuited through the leads; in short, all means were tried to cause a rapid destruction of the cell. The cells of the Cologne factory stood the ordeal best, and the firm obtained the contract. On examination the plates appeared in exactly the same condition as three months before. The active material was perfectly retained, and all the plates were straight. The author then discusses the relative merits of stations worked with accumulators charged by dynamos driven by slow-speed engines, and of those in which the current is supplied direct from dynamos coupled to high-speed engines, the verdict being in favour of the former.

ELECTRIC TRANSMISSION OF POWER IN UTAH.*

BY G. H. GUY.

The Wahsatch range, under the shadow of which Salt Lake City springs out of the plain, is studded thickly with water streams, fed by the springs and drainage of the mountain, the overflow from which has always been utilised by the Mormons for the fertilisation of their valley farms. Lake Blanche and seven other of the Wahsatch lakes, at altitudes of 11,000ft., to 13,000ft., are now being dammed, and converted into a power that will develop the resources of Utah in mines, products, and manufactures, to an extent almost unparalleled in the history of the West. The Big Cottonwood Power Company has practically completed its plans for the generation and transmission of electric power from the various water supplies in the Big Cottonwood Cañon, thirteen miles south-east of Salt Lake City, for the supply of light and power within the limits of the city and to the factories and small towns in the vicinity.

The power station is located in the Cañon, at "The Stairs," 14 miles by pole line from the distributing station of the Salt Lake and Ogden Gas and Electric Light Company, in Salt Lake City. At this station, there is a minimum flow of 3,400 cubic ft. of water per minute, which, working under 380ft. head, produces 2,447 H.P. During nine months of each year, it will give nearly 4,000 H.P. The storage reservoir at the head of "The Stairs" has an available capacity of 24 hours' continuous flow of the stream, making all of the water available by using an excess during maximum loads and allowing the reservoir to accumulate during minimum loads. 58,800 H.P. hours per day of 24 hours is looked for from this source, of which 68 per cent. can be delivered in Salt Lake City, in contract form, making 40,000 H.P. hours net daily. The 68 per cent. efficiency is derived from: Pelton water wheels, 80 per cent.; "G. E." generators, 94 per cent.; "G. E." transformers (raising), 97½ per cent.; line transmission, 95 per cent.; "G. E." transformers (reducing), 97½ per cent., or a total of 68½ per cent.

The outside dimensions of the generating station are 34ft. by 100ft. The generating plant consists of four 450-kilowatt three-phase "General Electric" generators, separately excited, non-compounded. Each generator is driven by one Pelton wheel, 60in in

* Abstract from the *Electrical Engineer* of New Yor

Digitized by Google

diameter, provided with two nozzles 3¼in. diameter. The straight nozzles are provided with a gate valve for shutting off, and the lower nozzle is equipped with a hood regulator, so that both good regulation and economical use of water are secured. Each nozzle, at 370ft. effective head, produces 310 mechanical H.P. at 300 revolutions. The water wheel is keyed directly on the armature shaft. In addition to the generators named, four 12½-kilowatt exciters, made up in two sets, will be used, both generators of each set being connected together by friction couplings, and each generator to be driven by a 14-in. Pelton wheel, with cast housings. Each set will consist of two generators, and two wheels will be built up on a cast-iron base-plate, making a rigid and direct connection. This application provides exciting energy in two units, and at all times either one or two exciters are in reserve. The exciters are to be run in multiple, and all connected to one common "bus line" on the switchboard. The three-phase generators will also be operated in parallel. There will be six raising transformers, 265 kilowatts each.

The poles for the line construction were selected from Sand Point (Idaho) cedar. The smallest are 40ft. long, and 8in. in diameter at the top. They are placed 100ft. apart. The line conductors consist of 12 wires—four circuits of three wires each, all No. 2 soft-drawn bare copper, and connected to the same common "'bus line" at the generating and at the distributing station. The line loss, in delivering 1,520 kilowatts at 10,000 volts, will be something less than 5 per cent.

The transmission line from generating to distributing station is 14 miles by pole line. The distributing station is owned by the Salt Lake and Ogden Gas and Electric Light Company, who rent it to the Big Cottonwood Power Company at a nominal rent. It contains, for "step-down" transformation, nine 175-kilowatt air-blast transformers, from the secondary side of which the Electric Light Company buys the current wholesale by meter. This arrangement is a most convenient one for both companies. The actual terms of the contract are that the Electric Light Company is to be supplied with all the current it can dispose of for electric lighting and power in units of 10 H.P. and under, the Big Cottonwood Company reserving the right to supply power to motors in units exceeding 10 H.P., and the right to reach such wholesale users of power by wires erected on the Electric Light Company's poles, throughout all the districts within the city limits. The contract begins January 1, 1896, and runs for a term of five years. Its conditions are that the current is bought at 2,000 volts, three-phase, at a stipulated price per kilowatt-hour, which will be used to supply electric light and power for any purpose up to 10 H.P., and for elevator service up to any limit desired by the lessees; 2,000,000 units annually is the minimum limit of the consumption of current.

The present production of the electric light company is practically 3,000,000 units per annum by the use of coal, after the usual central station methods, and the contract provides that as soon as the transmission power plant is in operation, the steam plant of the Electric Light Company is to be abandoned, the price to customers reduced, and other changes made that will be to the advantage not only of both companies but also to that of the public, by promoting the production of cheap electric power.

The final cost of the complete development is estimated at $300,000 (£60,000). An estimate of $300,000 for the original outlay for "The Stairs" would give for construction expenses—at 2,258 H.P.—$132.72 (£26. 10s.) per net horse-power delivered in the city ready for use. The Company's affairs have been so well administered that much more than half the power to be developed has already been disposed of absolutely, and the guaranteed total revenue from completed contracts is over $100,000 annually. Although the Company is confining its operations for the present to "The Stairs" supply, it has other valuable water rights partly developed by means of which it could at any time largely supplement its output.

The new distributing system, when complete, will consist of a network of primary mains with a network of low-tension secondaries. The primary mains will be at 2,000 volts. There will eventually be ten feeding points, though at first only six will be required. The secondary mains will be used almost entirely; only when the houses are very scattered will separate house transformers be used. In the commercial district, the secondary and primary mains will eventually be put underground, though this is not immediately contemplated. The transformers will be placed at street intersections in banks either fixed on the poles or in any suitable location near the intersection. Arrangements will be made for switching out alternate banks of transformers during light loads to save the waste of energy. The secondary mains will consist of three wires and a neutral wire. The voltage between any one of the three wires and the neutral will be 115. Motors, synchronous or non-synchronous, can be connected at any point to the secondary mains, or, when the motor is large, separate transformers will be used. It is intended to eventually use the alternating current for all arc lamps, in which case they will be connected to the secondary mains with small transformers.

The distributing station will be a substantial fireproof building, with a room for the 10,000-volt step-down transformers, a room for the 2,000-volt switchboard, and a room fitted up with instruments for testing and calibrating meters, &c. The current will be brought from the step-down transformer to the distributing board.

The change from the old to the new system will be no easy matter, and will have to be done gradually. In order to take the initial steps immediately three 150-kilowatt three-phase alternators will be driven by the existing steam engines, and will supply energy in the commercial district until the Cottonwood plant is ready. When the Cottonwood supply is established these generators will be used as synchronous motors to drive the arc-lighting machinery, and when the direct-current arc lamps are replaced by alternate-current lamps the machines will be available for use as motors wherever required. It is contemplated to use later on the old single-phase alternators as motors. In this way much of the old plant can still be utilised.

IS THE INVENTIVE FACULTY A MYTH?*

BY W. H. SMYTH.

To the ordinary mind a profound mystery appears to envelope the work of the inventor. He is looked upon with a species of awe, as one endowed by nature with what is known as the "inventive faculty"; a special organ or sense, having occult capabilities of inspiration and creation; a sort of automatic mental mechanism, needing only that its fortunate possessor should "touch the button" in order that, presto! the desired invention may instantaneously evolve from nothing. In fact, the great mass of even intelligent people of our age regard a noted inventor as nothing less—and nothing more—than a "wizard." As we go on, we shall see that this extraordinary delusion is shared, not only by the majority of inventors themselves, but in effect by the federal courts having jurisdiction in controversies relating to patents for inventions, as well as by the tribunals of the patent office. The intimate relations which it has been my fortune to sustain with many different inventors through a long period, and my experience in a capacity which may perhaps be regarded as that of a professional inventor, have led me to adopt certain views as to the nature and qualities of invention, and the mental processes of which the completed invention constitutes the tangible result, which in many respects are widely at variance with those which have heretofore found general acceptance. Whatever may be thought of the correctness of these views, it may at least be affirmed that, when formulated into a working hypothesis, they have enabled inventions to be conceived and worked out with no less certainty and accuracy of results than are common in other departments of science in which the phenomena and processes have been investigated, classified, and subjected to fixed laws. They have further led to the belief that not only is the popular conception of the mental operation of invention a wholly erroneous one, but that what is loosely termed the "faculty of invention" is one which is just as much capable of acquirement by proper instruction and cultivation as any other; in short, that, like carpentry or shoemaking, it is nothing more or less than an art. If these conclusions be well-founded, it is at once apparent that they tend to bring within the scope of scientific methods one of the most important departments of human endeavour, and one which, even in its present chaotic condition, has perhaps been the most important of all agencies in the advancement of modern civilisation.

I hold that that which is commonly termed the "inventive faculty" is nothing more than a combination of certain mental faculties with which every rational human being is endowed to a greater or less extent—namely, visualisation, memory, and reason.

The mental process involved in making an invention is analogous to that employed by the child in building with his toy blocks. Conceiving the idea of building some sort of house, he first arranges those which he thinks most suitable for the foundation, and continues by selecting from his store of blocks of various shapes and sizes those which he finds best adapted to form the various parts of the complete structure he has in mind. So too the inventor selects from the store of elementary mechanical parts or combinations with which memory has furnished his mind those which he regards as available for his purpose. The child builds and rebuilds; he changes a block here, and removes or adds a block there; so does the inventor, although in his case the mental operations of selection and arrangement are often so quickly and so automatically performed as to escape even his own observation. The material, too, with which the inventor works is infinitely better adapted to its purpose than are the blocks of the child with their unchangeable shapes and dimensions. It may be hard or soft, hot or cold, pervious or impervious, transparent or opaque, elastic or rigid, fluid or viscous; in short, it may be regarded as infinitely

* From the *Engineering Magazine*.

Digitized by Google

plastic, though possessing every other inherent quality known in nature or art. When confronted with a defect in his structure, the child is compelled to laboriously select from his heap of blocks, critically examining each one and trying its effect as a part of the whole; but the inventor's mass of material is of a much more manageable character. In an instant the panorama of memory is unfolded, and he makes his selection—a process which may be repeated not merely once, but a hundred times, while the hand of the child would be faltering over a single block. Among this material the mind of the inventor works as a modeller in infinitely plastic clay. With such facilities and such material why should not great results be accomplished? On the contrary, would not he be a bungler indeed who under these conditions should prove to be incapable of producing a worthy result?

Why, then, do we find the patent office at Washington to be a vast storehouse, filled with every conceivable form of foolish, silly, illogical, and useless contrivance? Why this immeasurable waste of money, time, and effort in the production of useless rubbish? Why is it that the very name of "inventor" has become a synonym for an irrational and cracked-brained enthusiast, and a title which the originator of an important or valuable device no longer cares to accept? The reason for this state of affairs is not far to seek.

Let us again revert to our illustration of the building-block, and add to the other conditions under which the child is compelled to work one more which is necessary to complete the analogy. Let us assume the blocks to represent, not only the actual things from which the inventor's conceptions have been derived, but his mental conception of those things. A very strange state of affairs now arises, which is due to the difference between the concept and the reality. It is as if, the instant a block were picked up for use, it should, wholly unperceived by the child, assume a distorted shape—the cube, for example, being no longer cubical, or the cylinder no longer cylindrical. The extent of the distortion, being a variable quantity, may range from an almost immaterial difference to the assumption by the cube and cylinder of the characteristics of each other, to say nothing of infinite possibilities of error in all other directions. Such an imagined distortion of the shape of the blocks is more than paralleled in the distorted mental impressions of exterior objects existing in the mind of the ordinary untrained observer; in fact, it is only the few who observe with even approximate accuracy, and still fewer who have the capacity to retain a correct mental impression of that which they have observed. Let the ordinary person attempt to make a drawing of, say, a round-topped table. After a careful examination, he will probably proceed to draw, to the best of his limited ability, a circle, and next, with more or less accuracy, the legs, ending upon a horizontal line intended to represent the floor. Now mark! the circle has been drawn, not because the impression of a circle has been made upon the retina of the draftsman, and so on his mind, but because he knows, or thinks he knows, that the top is circular. The fact that the legs rest upon the horizontal floor is quite sufficient to justify the delineator in his belief that he sees that which is not to be seen, and he represents it accordingly. Think of a man, no matter how quick in perception or how logical in mind, but with his memory stocked with erroneous conceptions like these, often not even rising to the dignity of caricatures of the external objects which they are assumed to represent! From such a mass of mental material is it conceivable that it would be possible to produce anything whatever which, when completed, should bear any logical relation to real things? Most certainly not; such a production could only find its fit place among the aggregation of abortive refuse which already encumbers the cabinets of the patent office.

The field of invention extends far beyond the narrow limits which custom has assigned to it; ingenuity and invention may be and are manifested, not alone in the works of the mechanician, but in those of the musician, the poet, the author, the lawyer, the physician, or the theologian. But, alike in the case of these and all other inventors, a certain mental equipment is an indispensable requisite to success. There must exist, first, an unerring and accurate perception of those similarities and differences which are fundamental in their nature; second, the capacity to distinguish the pertinent from the fortuitous in the particular problem under consideration; and, third (and this applies particularly to the mechanical inventor), the ability to clearly visualise, so that he may examine his structure as it progresses, and may select and, if need be, adapt, the elements he selects from his store, to the end that they may be co-ordinated with that structure.

The process of mind which I have termed "visualisation" is curiously exemplified in an incident which I will give as nearly as possible in the language of the narrator: "I have on several occasions surprised myself, so to speak, in the act of going through a mental operation which, for want of a better name, I will call 'manualisation'—that is, using mental hands to manipulate mental material. This has only occurred, so far as I can recall, on occasions when I have been struggling mentally with some aggravatingly refractory problem of mechanical detail, which, though really no more than a pretty little puzzle, has concentrated my attention until the entire mental effort was focussed on the rebellious point in strained and intense abstraction, the incomplete portion being in clear and sharp visualisation. Then, slowly, and as if with great effort, two hands would be laboriously pushed into view, and would take hold of the unfinished part and twist and shape it until it assumed a form adapted to the desired end. Then, like a flash, the strain would relax, the apparition vanish, and I would perceive myself to be a relieved, but exceedingly tired, individual. The visualisation, including the hands, would still remain in mental view for possibly a second or two after the completion of the work."

If it were true that the so-called "faculty of invention" is something unique and apart from other forms of mental activity, it would certainly seem as if its manifestations must be so characteristic as to be at once recognisable. Such, however, is by no means the case. Is it not a most suggestive fact that, while the question of the presence or absence of "invention" has constituted the sole and only issue in thousands of contested cases which have been passed upon by the patent office and by the federal courts, not one of these august tribunals has ever succeeded in laying down a definition of that which constitutes invention? Listen to the observations of a learned judge of the Supreme Court of the United States:—"The truth is, the word [invention] cannot be defined in such a manner as to afford any substantial aid in determining whether a particular device involves an exercise of the inventive faculty or not. . . . In a given case we may be able to say that there is present invention of a very high order. In another we can see that there is lacking that *impalpable something* which distinguishes invention from simple mechanical skill."* Is not this condition of mental confusion readily explicable, in view of the suggestion contained in the title of this Paper?

Prof. Robinson, perhaps the leading authority to-day, at least in the United States, upon questions of this kind, says: "The mental faculties employed in the inventive act are the creative, not the imitative, faculties. An invention is the product of original thought. It involves spontaneous conception of some idea not previously present to the mind of the inventor. Industry in exploring the discoveries and acquiring the ideas of others, wise judgment in selecting and combining them, mechanical skill in applying them to practical results—none of these are creation, and none of these enter into the creative act. Only when the mind of the inventor originates an idea new to himself, if not to all the world, does he call into exercise his own inventive skill, and perform the mental portion of the inventive act."†

If the above extract does not embody the popular conception of the nature and attributes of invention referred to in the first paragraph of this Paper, I am at a loss to know what meaning is to be attributed to it. I take direct issue with the propositions laid down by Prof. Robinson, and contend that the very qualities, faculties, and acts stated by him to be foreign to invention are those which constitute its very essence. It is assumed that something is *created* in the mind of the inventor; that something which had no previous existence is spontaneously generated there. On the contrary, I say that the mind of the inventor is a selective mental apparatus, in which material gathered from the outside is rearranged and adapted to new uses, and that this is nothing different from the normal operation of the human mind in all other operations. If this is not true, and if invention in fact is something other than this, then I can only say that the possibility has been demonstrated that, by the exercise of those faculties of the mind which are "foreign to invention" and those only, results may be produced which are absolutely undistinguishable from "invention of a very high order." If, on the contrary, my contention is well founded, and there is really no such thing as the so-called "inventive faculty," and if the act which we call invention is nothing more that the normal result of the operation of mental endowments of which all are possessed in a greater or less degree, it must logically follow that, inasmuch as our mental faculties are admitted to be no less capable of cultivation and improvement than our physical faculties, the power of invention or the capacity to invent may be improved and strengthened. It further follows that the operation of these faculties, like other processes, must be capable of being reduced to a definite system, governed by well-defined laws, with manifest advantage in respect to economy of time and effort and certainty of result.

Despite the unscientific and haphazard way in which these important results are attempted to be reached, we boastfully speak of the present time as the "Age of Invention." To me the past and present ages, as respects invention, seem ages of pure empiricism, which bear to the future and real "Age of Invention" much the same relation that the last century bears to the present in respect to theoretical and applied science. Examine at random any one of half-a-dozen lines of mechanical invention; one striking characteristic, common to almost all, instantly arrests the attention; they present nothing more than a mere outgrowth of the manual

* McClain *v.* Ortmeyer, 141 U.S., 419.

† "Robinson on Patents," Vol. I., Sec. 1, par. 78.

processes and machines of earlier times. Some operation, once performed wholly by hand tools, is expedited by some device which enables the foot as well as the hand to be utilised. Then power is applied; the hand and the foot operation, or perhaps both, are made automatic, and possibly, as a still further improvement, several of these automatic devices are combined into one. The fundamental basis is the old original hand process, and hence, except in the extremely improbable event that this was the best possible method of accomplishing the result, all the successive improvements are simply in the direction, not of real novelty, but of mere modification and multiplication. This inevitable tendency of the human mind to follow along well-worn grooves of habit serves to explain the reason of a fact often noticed—namely, that the most radical and important departures from old methods, by which many of the industries of the world have been completely revolutionised, are nearly always originated by persons wholly ignorant of the accepted practice in the particular industry concerned. There is no conservatism so unyielding as that of the specialist. It is one of the most insidious enemies which the inventor has to encounter; it is so easy to take things for granted, to let well enough alone. It is this and other considerations of no less significance that I have in mind when I say that the Age of Invention is not yet; we see only its vague and ill-defined fore glimmer. The ideal invention is as positive as a geometrical demonstration; hence the actual invention should at least be the logical mechanical complement of the conditions incident to the operation to be performed; it should be the logical answer to the problem which has been set, and should change only when external conditions change. Therefore an improvement on an invention should be of rare occurrence. The true and complete solution should be reached in the first instance.

I cannot close this line of argument without insisting upon the fact that the first and most important prerequisite to invention is an absolutely clear insight into, and a comprehensive grasp of, all the conditions involved in the problem. My own experience leads me to believe that this prerequisite alone constitutes nine-tenths of the work of invention, and that the remainder, in most cases, practically invents itself, or, to be more accurate, flows therefrom as a logical sequence.

And now, if it be admitted that invention is not an impalpable and indescribable "something," but that, on the contrary, it is the result of wise judgment and trained mechanical skill co-operating to select, combine, and apply observations and conceptions already accumulated, what then? My answer to this is twofold, inasmuch as it necessarily implies two radical and far-reaching departures from existing conditions. The first change should consist in eliminating from patent law and patent practice the conceptions which attach to the words "invention" and "invented," and in substituting therefor the ideas embodied in the words "discovery," "discovered," "produced," "thought out," "reasoned out." The mere change of phraseology would in itself go far to put an end to the existing maze of confusion, incident to the determination of the ever-recurring question whether a given device does or does not involve that undefinable "impalpable something" which the law says is the indispensable requisite to patentability, and would restrict the whole scope of the inquiry to the comparatively simple questions of novelty and utility. The second, and by far the most important, change should consist in the inauguration of a science of invention, with all the attributes which that phrase implies. Impressed as I am with the transcendent importance of this branch of the subject, I venture to offer such suggestions as have occurred to me, in the hope that others more competent may be induced to take the matter in hand, and give it the consideration which its importance warrants.

The following should form (in part) the basis of a scheme for the cultivation of invention: (1) Accurate and methodical observation. (2) Cultivation of memory, including the faculty of association. (3) Cultivation of clear visualisation; (4) logical reasoning from actual observations.

Particular importance should be attached to accurate observation, inasmuch as this is the indispensable foundation of all real education.

With the above considerations in view, a course of training in which the following exercises are included has suggested itself to me:—

First. Drawing from simple objects (not copies) under the following conditions: The object to be carefully examined, then removed, and a drawing made wholly from memory; this to be repeated until the last effort depicts the object as correctly as if drawn directly from it; each successive drawing to be on a separate sheet, and removed from view while the succeeding one is in progress; when considerable proficiency has been attained, more complex objects to be substituted, and the time-interval increased; the class of objects to have as wide a range as possible; as proficiency increases the time allowed for preliminary observation to be shortened, until the briefest possible glance at an object shall be sufficient to impress its appearance clearly upon the mind, the power of visualisation becoming so highly cultivated that at any future time the image may be called up and reproduced with absolute fidelity of detail; as a modification of the foregoing, drawing objects from description, oral and other.

Second. Other exercises of the same general character, with or without the aid of drawing, having reference to other characteristics than form, as, for example, material, structure, and function.

Third. The solution of problems pertaining to the construction of the sample object, its manufacture and improvement, together with the discovery of means for the accomplishment of definite ends. These are, of course, merely suggestions, the scope of which may be extended and modified almost indefinitely. It may, perhaps, be objected that while the first and second of the exercises above suggested might have the effect of cultivating the mental capacity for accurate observation, retentive memory, and clear visualisation, the third would often prove to be beyond the scope of the ordinary mind. That such is not the case I am able to show by citing as an example the invention of an actual machine of no inconsiderable utility for the purpose of assembling fruit cans in the process of manufacture. For convenience of description, the experiment is thrown into the form of a colloquy.

Q. Of what shape is a fruit-can?—*A.* Cylindrical.

Q. What is the principal peculiarity of the cylindrical form?—*A.* Roundness.

Q. What does this adapt it to do?—*A.* Roll on a plane surface.

Q. To provide means of conveying cylinders a short distance in the simplest manner, how would you proceed?—*A.* Make an inclined plane.

Q. Then, to convey bodies and heads of cans to a place to be operated upon, what would you provide?—*A.* Inclined planes.

Q. Suppose you had to unite two pieces of stove-pipe in the usual way; how would you go about it?—*A.* Hold them carefully opposite each other; then shove them together.

Q. Suppose you had to unite many such pieces of stove-pipe in lengths of two, and to do it quickly?—*A.* Fix something that would hold them opposite each other, and then shove them together.

Q. Now, with regard to the tops and bottoms of fruit cans; how would you assemble them?—*A.* The same as stove-pipes.

Q. How is that?—*A.* Let them roll down into something which will hold them in line with one another, and then shove them together.

Q. How will you make room for the next ones?—*A.* Let the finished ones roll away.

Q. How would you instruct a mechanic to build your machine?—*A.* Make three inclined runways, one for the can bodies and one on each side for the covers. At the lower end of the runways, make something that will hold these three things in line with each other. Then fix something that will push all three together, and make a runway for the finished cans to roll away.

Will anyone deny that the above course of reasoning is not within the capacity of an intelligent boy of 12 years of age, or that a mechanic skilled in the construction of such machinery could not build a practically operative can-heading machine from the above specification?

A course of instruction such as I have attempted to outline would serve to confer upon all capabilities now enjoyed only by the few, and would give to them such capacities for dealing with novel and unexpected problems and conditions as would vastly increase the productive capacity of the community. Language fails me in attempting to express my sense of the vast importance and urgent necessity of systematic culture and education in the direction which I have indicated. The science of invention should take its place as the first study in the kindergarten, and the test of proficiency therein should be the last one to which the student should be subjected before leaving his Alma Mater to struggle with the ever new problems which will surely confront him in actual life. It requires far more than the necessarily brief space which can be allotted to a magazine article to treat this subject in the manner which its importance demands, but I trust that enough has been said to show that such a course of training, if generally adopted, would vastly increase the dominion of man over the forces of Nature, and immeasurably hasten the advent of the real Age of Invention.

Electric Traction in Berlin.—An electric tramway, about 1¾ mile in length, connecting Pankow with Berlin, was opened for traffic on September 10th. The line is on the overhead trolley system, and was constructed by Messrs. Siemens and Halske. The conductor lies exactly over the centre of the rails, but instead of the trolley wheel sliding collector bars are used. The feeders are bare copper wires, 6mm. thick, and are carried overhead, fixed to the side poles which carry the span wires. The cars, which are for 30 passengers, run at a speed of from 9 to 12 miles per hour. The line has a double track, and the maximum gradient is only 1 in 300.

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

STEEL-PLATE PORTRAITS.

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; and William Sturgeon have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

THE RETIREMENT OF PROFESSORS.

As old age creeps on, even the most untiring engineer grows rusty. Be his intellect ever so nimble, his frame ever so wiry, his gait ever so active, there arrives a time when the unceasing march of science sweeps past him, and leaves him intellectually in the lurch. New ideas need new men. The brain, which at seventeen was teeming with novel conceptions, eager to follow the new clue, or lend itself to the untried process, is at seventy in a different condition to receive, assimilate, or even grasp ideas that do not follow along the habitual grooves of thought. Though the eye be undimmed, and the natural force unabated, something is gone that in earlier years made the man what he was. Veterans cannot pioneer. It is in the inevitable order of things, not to be changed by wealth, or weight of will, or, even by Orders in Council. Of no science, surely, is it more true than of electricity that its development has needed the mental pliability of youth. Certainly, the youth of some of its pioneers has been remarkable. But the very youths whose researches and inventions made them famous have in not a few cases notoriously failed to keep pace with the progress of discovery, and have in their later life fallen hopelessly to the rear. Each succeeding discovery has found a number of the earlier workers so fixed in their own order of ideas as to be incapable of adapting themselves to the new. Thus

Digitized by Google

the discovery by FARADAY of the property of specific inductive capacity, and of the curved shape of the lines of electric force, proved a stumbling block to the older electricians, who had learned to think only of forces acting at a distance in straight lines. Thus, again, FARADAY himself was entirely unable to understand the views of SNOW HARRIS as to the lightning discharge being conducted rather by the surface than by the whole cross-section of the conductor. Thus, too, when the telephone first compelled attention to the phenomena of alternating currents, many of the older electricians were puzzled to find that the simple law of Ohm no longer sufficed to calculate the flow in the circuit. Nay, is it not true in our own day that the strenuous objections which are urged against the use of alternating currents come from men who once were pioneers, but whom now the progress of the age is slowly but surely leaving stranded ? In another decade, perhaps, even the present pioneers will be left behind, incapable of grasping the ideas of the *nouveau siècle.* When Hertzian waves are used for universal signalling, lighting and power, and when Heavisidal units have superseded the ancient relics of the C.G.S., the now buoyant apostles of modern views will have lapsed into mere fogies of the old nineteenth-century type.

These reflections have been called up in the editorial mind by the appearance of a parliamentary blue-book on the subject of the compulsory retirement of professors. It seems that the rule according to which Civil servants on attaining the age of sixty-five are compulsorily retired had been taken to apply to the professors who hold office under the Crown in the colleges of the Royal University of Ireland, and who, like the professors of the Royal Colleges of Science in Kensington and Dublin, are nominally Civil servants. The compulsory retirement by the late Government of a distinguished Irish professor on reaching the limit of age gave rise to so much indignation, real or apparent, that a Committee was appointed by the Treasury to consider the question of superannuation of those who thus serve under the Crown. In passing, it may be noted that one of the Committee, Lord PLAYFAIR, is himself a retired professor of chemistry. The Committee recommend that there should be fixed rules as to superannuation of presidents and professors, and that they should be framed as College statutes, and not by way of an Order in Council. Their opinion is that when a professor reaches the age of sixty-five the president of the college should be bound to report to the Government the condition and efficiency of the teaching. If these are, and continue to be, satisfactory, the professor need not be superannuated till seventy, but at this age his retirement should be absolute. The report concludes with the following words: "As the professors are not appointed till middle life, the addition of seven years to their period of service in calculating their superannuation obviously tends to secure eminent specialists as candidates for office." No one can regard these terms as harsh. The professor is, from the first, freed from anxiety in the matter of receiving a fixed salary, even though it be small compared with that paid by a commercial firm to a confidential clerk, or by a fashionable draper to a head of a department; and that he should feel sure of a pension is an additional element in his favour, though here he is only in line with Civil servants of every branch.

But the concern of the electrical profession would be very small in this parliamentary report if it were measured by the half-dozen Government professors which it affects. It does not touch the majority of the professors in our universities, university colleges, and technical schools. Their income is not only a more precarious matter, but is not fortified by visions of a pension at the termination of their services. But neither are they frightened by the spectre of compulsory retirement. Lord KELVIN's tenure of his professorship at Glasgow has lasted all but half a century, and he has passed the three-score years and ten. But none would wish to deprive the University of Glasgow of the honour of his services, or wish him any other retirement than the long six months vacations which the Scottish Universities grant to their teachers. In Germany they manage things differently. The professor is not retired. He may celebrate his jubilee, and drag on in tenure of his chair, but shorn largely of his emoluments; for his income depends greatly on students' fees, and these, as his fame wanes, drop off. The students attend instead the lectures of some of the younger "extraordinary" professors, who are licensed by the university to teach, and in a measure to compete with the "ordinary" professor. Doubtless the system has it advantages. Doubtless also its hardships.

In the case of the holders of professorial chairs in the modern university colleges and technical colleges of England, we believe none of these are appointments for life. None are highly paid compared with the holders of chairs at the older universities, or with the chairs in Edinburgh or Glasgow. None, indeed, have any pensions attached to them. And in some instances, notably in some of the earlier appointments of the City and Guilds Institute, the very wholesome condition was attached that the holder was expected to remain in professional practice while carrying out the duties of his chair. Only so could the colleges be sure of getting the services of a real live worker, in touch with his profession. This clause, too, presents another side; for while a kind of spurious dignity attaches to the appellation of "professor"—in compensation, we suppose, for the limited remuneration attached to his office—he is often tempted to quit his teaching for more lucrative work. We know of one distinguished ex-professor in London whose professional income immediately doubled on his laying down his professorship; and probably similar results would occur in the case of others, in whom, however, the passion for teaching is too strong to permit them to lay aside a work which seems to others little less than drudgery. It would be invidious to particularise; but we venture to think that the science and the practice of electricity in England, and particularly in London, owes more to its professors, old and young, than many are willing to admit. The names of DANIELL, of GROVE, of FARADAY, of MAXWELL—to name no others, dead or living—will be imperishable in electric science. And they were—only professors. FARADAY, indeed, seems to contradict the notion that progress and discovery are the prerogative of the young. It was not till the age of 31 that he discovered the liquefaction of chlorine—not until the age of 40 that he discovered the induction of electric currents by magnetism. When he was 46 he discovered specific inductive capacity. At the age of 54 he made the observation of the rotation by the magnet of polarised light, and followed this up with his investigations of diamagnetism. When 56 he wrote the "Thoughts on Ray-Vibrations," which MAXWELL described as FARADAY's electromagnetic theory of light. GOETHE at 80 writing his "Faust," or GLADSTONE in retirement writing on BUTLER, present exceptions to the general rule. But to few men is it given to preserve to a green old age such a youthful elasticity of brain. Science has had, and still has, its grand old men. Yet in nine cases out of ten it had been better had some happy scheme of superannuation brought younger men to fill a post needing strong vitality for the adequate performance of its duties. For in technics, even more than in pure science, superfluous lags the veteran on the stage.

REVIEW.

The Steam Jacket Practically Considered as an Efficient Fuel Economiser. Second Edition. By WM. FLETCHER. (London: Whittaker and Co. 1895.)

The principal details of a steam engine have become so highly differentiated, and the theories of their action are developed into so amazing a complexity, that it is no wonder that each individual organ claims a text-book of its own. A separate treatise devoted to the steam jacket is at once a good idea and a useful development of the literature of the steam engine; and we are glad to see that Mr. Fletcher has made an essay in this subject an addition to Messrs. Whittaker's generally admirable "Specialist Series." There is no doubt that a reliable and sufficiently comprehensive treatise on the steam jacket, which should take into account on the one hand the modern researches of Bryan Donkin, and on the other hand the practical work done by Willans and others, was wanted. The only question is, whether Mr. Fletcher's book has satisfied this want. In our opinion it only partially and incompletely satisfies it; though, we hasten to say that there is a great deal of useful information to be found in this book. The author, indeed, is happier and more accurate in his practical treatment of his subject than in his attempt to formulate a theory.

To provide a theory of the steam jacket, Mr. Fletcher goes back to the pages of an engineering contemporary in the year 1871, and extracts a ready-made hypothesis, which he puts forward with due approbation and blessing as the "whole theory." Here it is:—

"All the liquefaction due to the performance of work by the steam within the cylinder is transferred to the steam within the jacket. The water resulting from this liquefaction is restored to the boiler, where it is re-evaporated, and flows to the cylinder to do more work; whereas, if the liquefaction had taken place within the cylinder, the resulting water would have been re-evaporated there instead of within the boiler, and the resulting steam, although obtained at just the same expenditure of power, would, instead of doing work on the piston, do it in heating the condensing water. It thus appears that, in a properly jacketed engine, *the true seat of the entire energy of the engine is in the jacket, and not in the cylinder*; and, startling as the statement may appear at first sight, it is none the less virtually true, that it is *in the jacket, and not in the cylinder, that all the work of the steam is performed*. It follows, as a consequence, that the condensation which takes place in the jacket does not in any way represent loss of fuel, except in so far as that condensation is a result of radiation and conduction through the sides of the cylinder to the condenser during the time the exhaust port is open, and of radiation to the external atmosphere."

(The italics are in Mr. Fletcher's book.) Now, this antiquated "theory" is a strange and incongruous admixture of half-truths with utterly erroneous and preposterous assertions (those, oddly enough, in the italics), the whole being bound together with a specious but fallacious logic. It *is* true that the steam jacket prevents wasteful liquefaction in the cylinder, by permitting liquefaction to go on unwastefully, or rather, far less wastefully, within itself. But to argue from this that the whole work of the engine is done by the jacket steam is simply to arrive at a totally wrong conclusion by an illogical argument based upon an inadequate, not to say irrelevant, premise.

Nor is the author any more happy in the details of his theory. For example, in explaining radiation he makes the quite erroneous statement that—

"The rapidity with which heat radiates varies, other things being equal as the square of the temperature of the hot body is in excess of the temperature of the cold one, so that a body if made twice as hot will lose a degree of temperature in a quarter of the time; if made three times as hot, it will lose a degree of temperature in one-ninth of the time; and so on, in all other proportion. The loss of radiation is not affected by the form of the radiant body: a cube or cylinder will radiate the same amount of heat with equal areas under the same conditions."

It is hardly necessary to say that the author is entirely wrong here; besides which, he confuses between the rate of radiation from a surface (at a steady temperature) and its rate of cooling when not supplied with heat; two considerably different phenomena.

We fear that Mr. Fletcher has exaggerated a laudable desire to make prominent the virtues of the steam jacket, into an attempt to make its value pre-eminent. From the thermodynamic point of view, he almost wishes us to believe that to be a steam engine is to be a steam jacket. Little wonder, then, that he has no patience for unjacketed engines; neither is it altogether surprising that he ventures to attack the electrical engineer for his practice in using high-speed engines of this class. Here is the amusing tirade in which he expresses his views in this matter:—

"We regret to say that small unjacketed vertical engines are now being most extensively adopted for driving dynamos for electric lighting purposes, and the amount of steam consumed by some of these wasteful abortions is, we believe, never realised by the users, and known only to those who have tested the engines, or to others who have had the privilege of stoking the boiler supplying them with steam."

Electrical engineers who have been using "these wasteful abortions" can afford to smile at these mistaken views. Their author is evidently quite unacquainted with well-established facts. Yet it is regrettable that Mr. Fletcher has not put to better use the mass of practical data which apparently he has had at his disposal. Had a scientific and impartial attitude of mind been taken by the author, and had he taken the trouble to acquaint himself with the latest technical research on this subject, he would have produced a work possessing quite ten times the value of the one before us.

The author's account of the history of the steam jacket is complete and interesting. He traces its development from the time of Watt, points out the early misconceptions and failures in practice, and shows how this useful appendage to the modern steam engine has gradually arrived at its modern efficient condition. He tells, in a later chapter, a story which we cannot refrain from repeating, as it well illustrates the erroneous ideas of the function of a steam jacket, which characterised its earlier as well as its later opponents:—

"Some little time ago a well-known engine maker was asked if the cylinder of a steam engine we were looking at was steam-jacketed. He, placing his hand on the cylinder lagging of the working engine, said, 'There is no need for a steam jacket, as the loss of heat is very slight.'"

Three important chapters are devoted to "The Abuse of the Steam Jacket," and in these the author has many practical things to say, as to how a jacket should be constructed and worked if it is to do good instead of harm. Here are some experiences gained by Mr. Coath, which he repeats:—

"In thirteen steamers *he found the drain pipe full open to the condenser*, and the steam supply cock to the jacket partly open. In three steamers the jackets were only used on starting to warm up the cylinders, and, when the engines were well under way, the steam supply was totally closed, *and the outlet opened to the condenser*. In two cases the inlet was left wide open, *and the drain pipe kept closed, and the condensed steam was blown out once a watch.*"

We have not space to make any further detailed comment on Mr. Fletcher's book. In conclusion we can say that, despite that in theory it is defective, as a practical treatise it is excellent, and as a book to read it is simply charming.

THE HEATING OF DYNAMOS.

BY ERNEST WILSON.

It is usually stated in the temperature specification of a dynamo that after it has run for six hours at full output the temperature shall not exceed a given maximum. Apart from the bearings this, of course, refers to the armature and magnet windings. For instance, the Admiralty specification lays down a maximum rise of 70°F. above the temperature of the room.

When an armature is rotating in a magnetic field and delivering its current to the external circuit, or receiving a current from the external circuit, there are in it four causes for dissipation of energy:—

(1) The armature current itself, in virtue of the electrical resistance of the armature conductors;
(2) Magnetic hysteresis;
(3) Induced currents in the iron of the armature;
(4) Induced currents in the armature conductors.

Since the ultimate temperature to which an armature will rise for given conditions as to speed, radiating surface, and temperature of surrounding atmosphere, is a function of each of the quantities (1), (2), (3), (4), it is our duty first of all to determine these under given conditions.

Taking them in order:—

(1) is easy to determine if the resistance of the armature and its current are known.

Digitized by Google

(2) is easily dealt with from the known magnetic qualities of the iron of the core if we make this assumption : that the dissipation of energy by magnetic hysteresis is the same whether the magnetism of the core is reversed by diminishing and increasing its intensity, or whether it is reversed by turning round its direction without reducing its amount to zero.

(3) and (4) are more difficult to handle; in regard to (3) we make the same assumption as in (2).

Before going further it will be well to give the results of a simple experiment with the machines* in the Siemens Laboratory, King's College, London these being specially referred to in this Paper. Their axles being rigidly coupled together, one of them was arranged to run as a motor at varying speeds, the power delivered to it being measured at any time. The other had its brushes carefully set on the neutral line and connected to a voltmeter; its field could be varied in magnitude and its exciting current made or broken at will. The speed was measured on a Buss tachometer.

The method of test was as follows: the motor was run at, say, 1,000 revolutions per minute, the generator not excited, and the watts delivered to motor noted. The generator was then excited, its volts noted, and the watts given to motor again noted, the speed being kept constant. Finally, the exciting current of generator was broken, and the watts again taken as a check upon their former value.

From the volts on generator armature and speed we are able to deduce induction per square centimetre in armature, and the

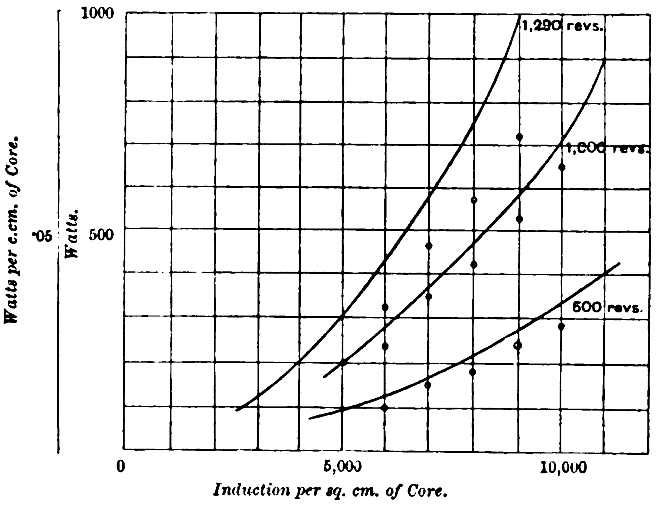

Fig. 1.

difference between the watts taken to drive the combination, generator excited and not excited, can be taken roughly to be the rate of dissipation of energy due to causes (2), (3), (4).†

The full lines in Fig. 1 give the watts dissipated in terms of maximum induction per square centimetre **B** for 500, 1,000, and 1,290 revolutions per minute respectively. Fig. 2 gives another aspect of the same thing—that is, for a given **B** the watts dissipated in terms of revolution per minute or frequency in periods per second.

It is necessary to state here that the armature core consists of soft iron discs not specially insulated from one another, except only by any oxide or dirt that may be between them, compressed together by means of screwed plates on the shaft.

Their thickness may be taken to be about 1mm.; they have, when allowance is made for the shaft, from which they are not insulated, a cubic capacity of about 9,450 cubic cm. and a cross-sectional area for induction of 518 square cm.

It is clearly our object, when determining *à priori* the losses in an armature core, to pre-determine the curves given in Fig. 1, and then, given a suitable relation between total watts dissipated, radiating surface, and circumferential velocity, to predict the ultimate temperature, or the temperature after any time, of the armature.

The relation between the dissipation of energy by induced currents in ergs per cycle per cubic centimetre and maximum average induction per square centimetre **B** for two frequencies has been found* in the case of a cylinder of very soft Whitworth steel 4in. diameter, and is shown in the curves *a* and *b* (Fig. 3). Curve *a* gives this relation with 20 seconds periodic time, and curve *b* with 80 seconds; or frequencies of $\frac{1}{20}$th and $\frac{1}{80}$th of a period per second.

Since similar magnetic events will occur in bars of different diameters for the same material at the same temperature, but at times varying as the square of the diameters, these same curves can serve also for cylinders of other diameters. In the core of our armature we have plates instead of circular wires, and since a plate in regard to induced currents in its substance is roughly comparable to a wire having a diameter double the thickness of the plate, these results can be used also for plates. Fig. 4 gives another aspect of the curves in Fig. 3—that is, for a given maximum average induction per square centimetre, the relation between ergs dissipated by induced currents per cycle per cubic centimetre, and frequency, or revolutions per minute, in the case of a two-pole machine, is given for a given thickness of plate in millimetres.

Although the 4in. cylinder is not of the same material as the plates in our armature, we may form from these curves a rough idea of the dissipation of energy by induced currents in the core.

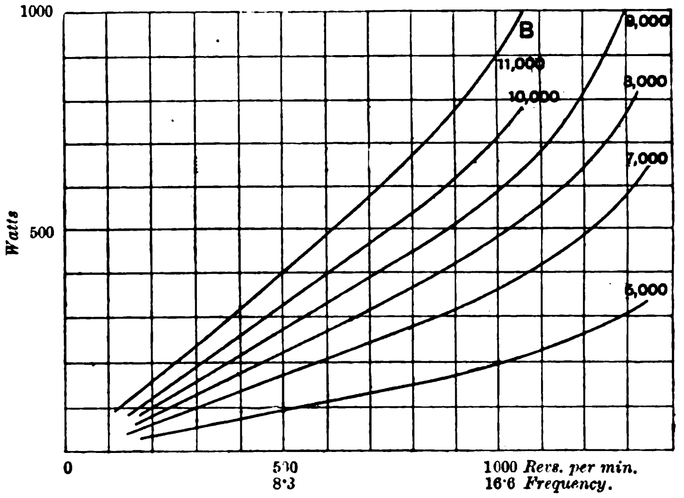

Fig. 2.

Let us, then, see if we can reproduce the curves in Fig. 1 from an assumed relation between maximum **B** and the ergs dissipated per cycle per cubic centimetre $\left(\frac{1}{4\pi}\int \mathsf{H}\, d\,\mathsf{B}\right)$ due to magnetic hysteresis, and the curves in Figs. 3 and 4 for induced currents.

The figures are tabulated in Table I., and explain themselves. They give the total core losses due to hysteresis and induced currents at the three speeds 500, 1,000, 1,290 revolutions per minute.† These ordinates have been doubled before plotting, in order the better to compare the form of the curves, and are shown for each speed thus: 0 in Fig. 1.

It will be observed that in each case the form of the curves is similar, but the ordinates are less than half what would be required to make the calculated and observed watts agree.

There are reasons why these curves should *not* agree, even supposing that the data for hysteresis and induced-current losses were obtained for the particular iron of the core itself:—

(*a*) We have not taken account of the induced currents in the copper conductors of the armature; this can be made a

* For a full description of these machines see *Proc.* R.S., Vol. LI., p. 49; Hopkinson's "Dynamo Machinery"; or *The Electrician*, April 8, 1892.

† The dissipation of energy due to induced currents in the pole-pieces with our smooth armature and any increase in the bearing friction there might be due to magnetic pull are neglected.

* See *Phil. Trans.*, R.S., Vol. CLXXXVI. (1895) A, pp. 93—121; also *The Electrician*, February 22, 1895.

† It is obvious that in cores where the induction density is greater—say 16,000 or 17,000 C.G.S. units per square centimetre for the same frequency—that the plates should be much thinner or better insulated from one another if the temperature is to be kept down.

Digitized by Google

small quantity by proper construction, and is small in our machine.

(*b*) The core plates are not specially insulated from one another, and therefore there is much greater conductivity than we assumed in the first instance. This is probably the principal cause of the difference between the observed and calculated watts in Fig. 1.

(*c*) There is the loss in the steel shaft due to hysteresis and induced currents.

(*d*) The magnetic pull on armature, which is small.

For the same copper conductors it is simply a question of extra expense to ensure better insulation between the plates, as against a small gain in efficiency consequent upon a lower ultimate temperature of the armature. *Given* that the plates are perfectly insulated from one another, we have still the induced currents in the conductors and the loss in shaft to deal with in applying the above process of calculation. Further than this, when the machine is loaded there is a considerable variation of induction density on account of armature reaction,* and this would again increase the losses due to hysteresis and induced currents for the same maximum average total induction. The conductivity of the core would be decreased by rise in temperature of the armature, thus lowering the induced-current

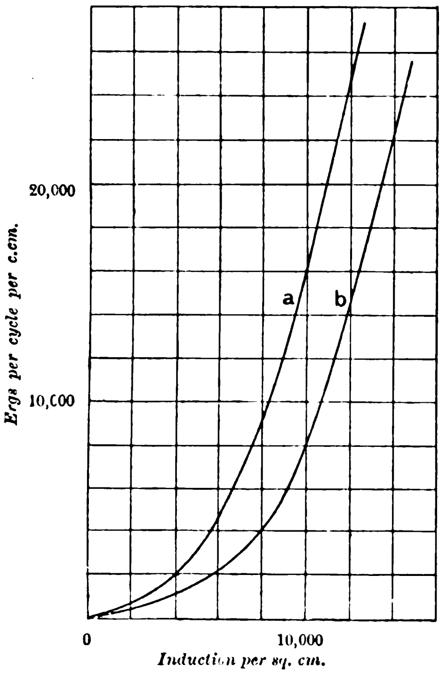

Fig. 3.

losses; but the expansion of the plates in our core might again increase conductivity.

Unless the plates are perfectly insulated, and the relations for hysteresis and induced currents above discussed be known for the particular iron, the problem is complicated. A careful experiment was made to see if the curves in Fig. 1 are much altered by change of temperature of the armature. It shows that for a rise of 42°F as shown by a thermometer at commutator end of armature, at a speed of 1,000 revolutions per minute and B in armature about 8,000, no sensible change is produced.

If reference be made to *Engineering* for March 24, 1893, it will be seen that in these machines the losses due to causes (2), (3), (4), together with the friction in the bearings and brushes and wind friction, vary from 5 to 6·6 per cent. of the total power given to the machine as generator and motor, the total watts by Method II. from these causes being 1,520. The curves in Fig. 2 give the watts due to causes (2), (3), (4) as 430 in generator and 550 in motor. Adding these and subtracting from 1,520, we have 540 watts due to bearing, brush, and wind friction, which we can equally divide between the two machines. So that 1 or 2 per cent. might be gained by insulating the plates.

* See *Proc.* R.S., Vol. LI., p. 49; Hopkinson's "Dynamo Machinery"; or *The Electrician*, April 8, 1892.

The temperature of armature and magnet windings of a dynamo is in practice a difficult subject to deal with, on account of the varying conditions under which dynamos have to work; but in order to give some idea of what might be expected from these machines, the following experiments were made:—

The armatures were uncoupled, and one of them fixed so that it could not rotate, the other being driven by a steam engine. The exciting current of the driven dynamo was measured by a Siemens dynamometer, and kept constant; the machine was run for six hours at constant speed, its current being passed through the stationary armature, a Thomson balance, and extra resistance to take the load.

Every hour the dynamo was stopped, and by means of a Thomson double bridge* the resistance of its armature was measured between opposite segments of the commutator (the same segments being always taken); the other armature was treated in the same manner, and the temperatures of the two armatures were taken by a thermometer. The resistance of the armatures at 20°C. was in each case 0·0416 ohms. The resistance of the magnet coils of the generator was measured by means of a Wheatstone bridge, the temperature being also noted by a thermometer. The time between stopping and starting again was about 5 minutes. Table II. gives the results of the tests.

It is usually assumed that the practical ultimate temperature to which a magnet winding of given dimensions, and wound on the limb in a given manner, will rise, can be expressed as

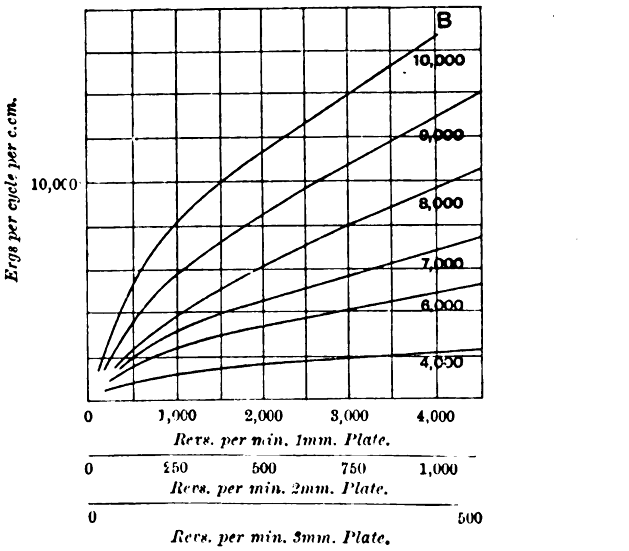

Fig. 4.

follows†:—$t^0\text{F} = \dfrac{a\,\text{W}}{\text{A}}$, where t = practical final temperature, W = watts dissipated in winding, A = radiating surface in square inches, and a being a supposed constant. It is obvious that some convention must be come to in estimating A. With regard to the magnet windings, the two surfaces between them are neglected, and the distance right round the two windings as they stand is multiplied by the height between the wooden formers—these dimensions are 70in. and 12in. respectively, there being no ventilating space between limb and winding. The depth of winding is 2in. For the armature we have taken the total area in square inches of a cylinder, the length of the armature not including commutator and its radial connections; this comes out at 619 square inches, the length being taken as 20½in. and diameter 8in.

When an armature is rotating and delivering a current to the external circuit or receiving a current, we have stated that there are losses in it other than those of current squared into resistance. In these tests the average B has been found in the usual way for the rotating armature, and from curves in Fig. 2 the watts due to hysteresis and induced currents have been estimated.

*See *Engineering*, August 19, 1892.
† This subject is fully treated in "The Dynamo," by Hawkins and Wallis.

* Taken from Test I. on account of current being the same.

The formula $t^0\ \mathrm{F} = \frac{a\,W}{A}$ must be modified on account of rotation; if the rotation is zero, as is, in fact, the case in our stationary armature, we can use this formula, and the modification might be stated thus* $t^0\ \mathrm{F} = \frac{a\,W}{A\left(1+\frac{b}{c}\right)}$, where b = circumferential velocity of armature in feet per minute, c being a supposed constant.

Coming to the results of the tests we see at once a difference between temperatures taken by means of thermometers and average temperatures got from a determination of resistance. The thermometer was placed some minutes before stopping on the stationary armature, but was in the case of the other only in contact about three minutes. The temperature varies at different parts of the surface of an armature, the commutator and its radial connections having a cooling effect. Experiments show that in the case of the stationary armature the commutator end differs in temperature from the other by about 5°F. for a current of 69 amperes in the armature. But in the case of the rotating armature and the same current, there is the fan action of the radial commutator connections, which makes this difference about 9°F. by thermometer. All the temperatures of armatures given in Table II. as taken by thermometers were taken at the commutator end of armature. In our case no special means are provided for ventilation. Thermometers with small thermal capacity should be used.

* This formula is the same as in Messrs. Hawkins and Wallis' "The Dynamo."

The results show that after about six hours the temperature for given conditions is fairly constant; this is not necessarily the case, and, *cæteris paribus*, the larger the machine the longer will it be before it becomes fairly constant in temperature. Then, again, the whole subject is greatly complicated by the varying temperatures of the rooms where dynamos have to work.

Table III. gives the constant *a*, *c*, and other particulars of the tests given in Table II. It should be noted in connection with the test of stationary armature and small current that the results are not so reliable on account of the small rise in temperature above atmosphere.

In conclusion, I wish to express my best thanks to Messrs. Cobb, Evans, Makovski, Shawcross and Welbourn, student demonstrators in the Siemens Laboratory, King's College, London, for their assistance in these experiments.

Telegraphic Communication between England and Germany. The *Kölnische Zeitung* of Cologne is complaining of the delays which have for some time been occurring in the transmission of messages from England, especially in connection with market reports from London, Liverpool and Glasgow. A few days ago the newspaper in question received a telegraphic message from the latter city, the time occupied in the transmission of which was no less than 3½ hours. The blame is being laid on the English authorities, and the German Government is being urged to take steps to improve or extend the telegraph facilities between the two countries, with the view of obviating these delays.

EXPERIMENTS ON THE TRANSFER OF HEAT THROUGH PLATES WITH VARIOUSLY ARRANGED SURFACES.*

BY WILLIAM G. WALKER, M.INST.M.E., A.M.INST.C.E.

The object of these experiments is to compare the effect on the transfer of heat of variously arranged surfaces projecting from the primary surface of a plate in contact with steam, air and water.

Two cylindrical smooth vessels were constructed of exactly similar dimensions, cut from the same brass tube, each $6\frac{3}{4}$in. length,

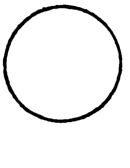

FIG. 1.

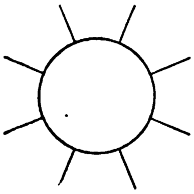

FIG. 2.

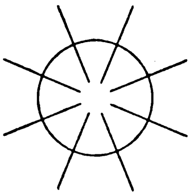

FIG. 3.

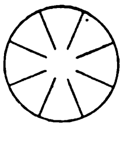

FIG. 4.

$2\frac{1}{16}$in. external diameter and $\frac{1}{32}$in. thick; they were fitted with movable water-tight lids through which thermometers were inserted. When filled with water no difference was found to exist between their respective powers to absorb or discharge heat; this

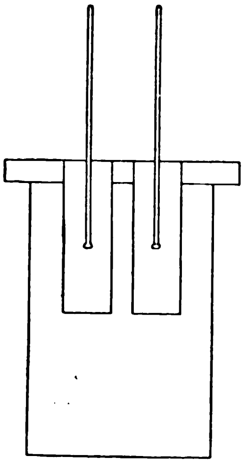

FIG. 5.

was ascertained by heating them together in steam to 212°F. and allowing them to cool either in air or water. Both the thermometers registered the same number of degrees at all points of the scale. One of the cylindrical vessels was then tried with copper ribs $5\frac{1}{2}$in. long, $\frac{3}{4}$in. wide, and 0·012 thick, soldered on

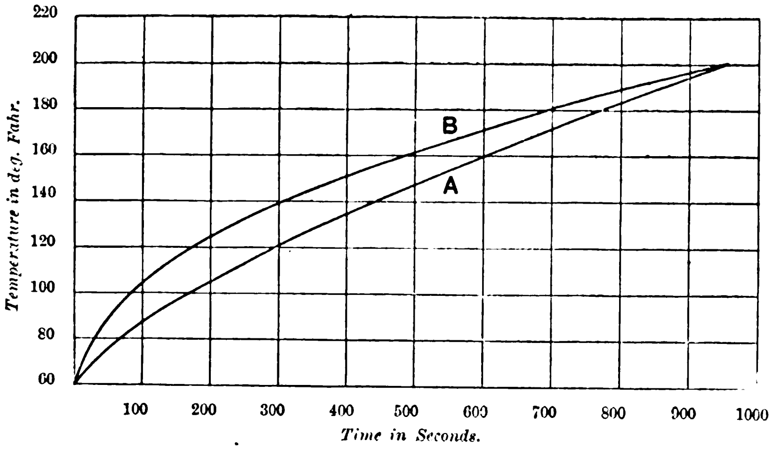

FIG. 6.—Temperature raised by contact with Steam. A, Plain Surface. B, Ribbed Surface.

longitudinally. The ribs were spaced equally and radially round the cylinder, and were tried internally and externally (*see* Figs 1 to 4) as follows: (1) Eight external ribs; (2) sixteen ribs, eight external and eight internal; (3) eight internal ribs.

* Paper read before the British Association at Ipswich, Section G.

When on together the external and internal ribs were in the same plane. The heating of the two vessels was accomplished by suspending them in a tin vessel 12in. high and 8in. in diameter (*see* Fig. 5) having two inches in depth of water kept boiling by a powerful burner. The lid of the tin vessel was a movable one of wood, to which the tops of the cylinders were attached, the thermometers protruding through.

Mode of Experiment.—The two cylinders to be compared were filled with water, and when their temperatures were equal, generally about 65°F., the wooden lid to which they were attached was placed on the vessel containing boiling water; the lid was a good fit, and the metallic surfaces at once commenced to absorb heat. The reading of the thermometers, together with the time,

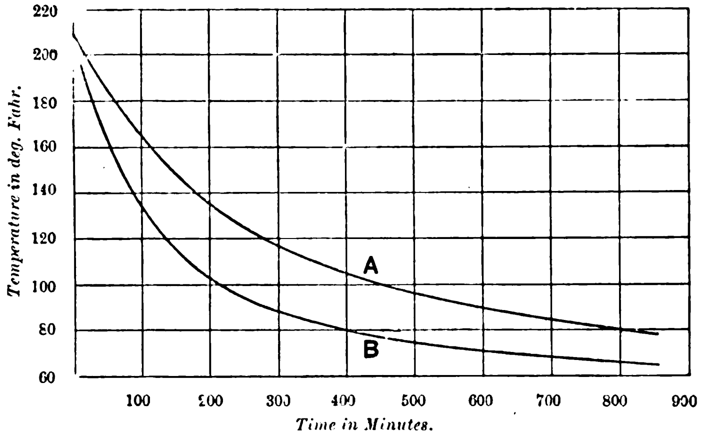

FIG. 7.—Temperature raised by contact with Air. A, Plain surface. B, Ribbed surface.

was noted simultaneously at every 10deg. of the plain cylinder; the time was taken in seconds by a ship's chronometer, and the temperature to one-fifth of a degree; the thermometers became stationary at 210°F. The lid was then, together with the cylinders, lifted off and suspended either in air or water, and allowed to cool down, the respective temperatures and the time being noted simultaneously at every 10deg. It will be understood that contact with steam, air or water always refers to the external surface of the cylinders, the internal surface being, of course, exposed to water only. The difference which arose in the conditions between some of the experiments due to the variation in the supply of heat from the burner, change in the atmosphere, temperature and cooling water, does not affect the value of the comparative nature of the experiments, as any change had the same effect on each cylinder.

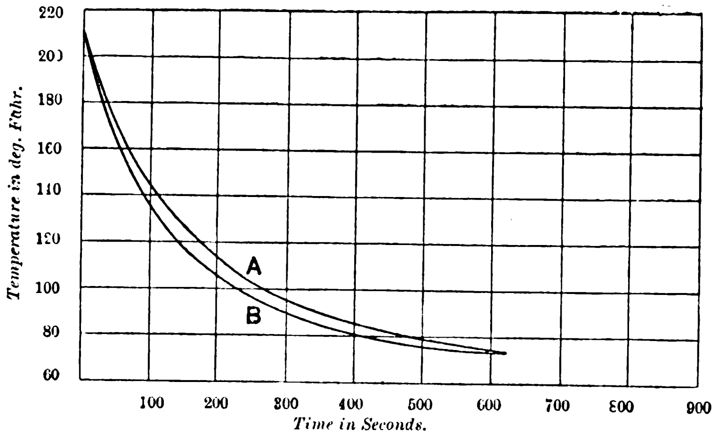

FIG. 8.—Temperature raised by contact with Water. A, Plain surface. B, Ribbed surface.

Examination of Results.—The results of the experiments are given in Tables I. to III.; they are shown plotted for the externally-ribbed cylinder in Figs. 6 to 8. It will be noticed that the difference between the temperature of the corresponding plain and ribbed cylinders increased from zero and reached a maximum after a certain time, after which they again closed to equal degrees of temperature.

The presence of the ribbed surfaces increased to a considerable extent the rapidity of transfer of heat either when absorbing heat from steam or discharging it into air. With the ribbed surface in contact with water, the speed of transfer was also increased, but not nearly to so great an extent. In the case of the externally-ribbed cylinder (Fig. 2), the greatest difference in temperature

between the corresponding plain one was 18°F., 33°F. and 8°F. respectively when in contact with steam, air and water. When exposed for 53min. in the atmosphere, the temperature of the externally-ribbed cylinder had fallen 102°F., whilst the temperature of the plain one had only fallen 69°F. The addition of the internal ribs to the external ones (Fig. 3) appeared to produce little or no effect on the result previously obtained. The temperature of the externally and internally-ribbed cylinders (Fig. 3) showed a maximum difference of 18°F. and 33°F., compared with the plain cylinder, when absorbing and discharging heat in steam and air respectively. In the case of the internally-ribbed cylinder (Fig. 4), the external ribs having been taken off, the maximum difference in temperature over the plain cylinder was 1°F., 1°F. and 6°F. in steam, air and water; their outer or external surfaces were, of course, the same in this case.

It is interesting to notice the greater effect of internal ribs in the case when the cylinder is cooled in water; the comparative slow transfer of heat when in contact with steam or air would allow the temperature of the water in the cylinder to adjust itself. When however, the transfer became comparatively rapid, the ribs became more effectual. The external ribs were more effectual in discharging heat to the atmosphere than in absorbing it from steam; this difference may be due to the condensed layer of steam which was deposited on the surface, and which retarded to some extent the transfer of heat.

The external surface was also increased by coils of copper wire $\frac{1}{16}$in. and $\frac{1}{32}$in. in diameter; with a space between the turns from a mean of nine experiments, the temperature of the coiled cylinder fell faster than the plain one, reaching a maximum difference of 6·7°F.; when, however, absorbing heat from steam, the effect was reversed, the temperature of the plain cylinder rising the fastest and reaching a maximum difference of 4·7°F. This apparent irregularity can be accounted for by the thick layer of steam which was deposited between the wire coils, and could not easily drain off. When cooled in water, the two cylinders, coiled and plain, gave the same results.

In these experiments care was taken that the colour of the respective metallic surfaces was the same.

TELEPHONIC EXPERIMENTS WITH BARE CONDUCTORS LAID ALONG THE GROUND.*

For many years bronze wire has been used by the German Postal Telegraph Administration as a conductor for telephone lines, on account of its conductivity being superior to that of the usual iron or steel wires. Besides bronze wires covered with copper, a number of German makers have also brought out numerous double-metal wires, under the names of compound wire, bi-metallic wire, double-metal wire, double-bronze wire, and patent bronze wire, &c. These wires have a core of steel or aluminium-bronze, with a high tensile strength, and are covered with copper or bronze of a high conductivity. Experiments with these wires were made in order to see if they could compare with bronze wire for telephonic purpose, both in respect to their mechanical and electrical properties. It is claimed for these compound wires that they have important properties. For example, a telephone line with a bimetallic conductor will work much more perfectly than with a conductor of a single metal such as copper. Again, it is claimed that less insulation is needed for such a conductor than for copper or any other material, and hence such wires laid on the earth without special insulation permit of telephonic communication to a much greater distance. The experiments conducted for the German Post Office by its telegraph engineers gave the following results:—

Experiments A.

Experiment 1.—Four wires of different composition and size, and about 0·5 kilometre in length, were laid as shown in Fig. 1 along a ditch 10 metres broad and 0·6 metre deep to be found on either

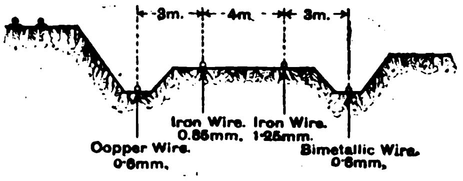

Fig. 1.

of the Grunewald railway station. Although it had rained hard the day before, the ground was only slightly moist, on account of its sandy nature, and the surface was quite dry. There was no difference in the dampness of the ditches and protecting ridge. At each end the wires were connected to a switch which was connected to a telephone, so that by revolving the switch each of the wires in Fig. 1 could be connected at will to the telephone. The other end of the telephone coils was connected to a 6mm. galvanised iron wire, which was driven half a metre into the ground, and served as an earth.

As no difference in the sound could be discovered under these circumstances, the length of the four wires was increased to one kilometre.

Again, no difference was observable even when at about 100 metres from one end. The four wires were laid in a hole 1 metre long and ½ metre deep, and covered with the damp soil dug out of the earth. The transmission was in each case very good, although there was no discernable difference between the four wires.

Tests with longer lengths were not considered necessary, but a further experiment, with part of the wires laid in water, was made.

Experiment 2.—For this purpose a bay of the "Krummen Lanke" was chosen, and about 150 meters of the double metal wire and copper wire laid in it. In this case there was no transmission at all. If the two wires were drawn taut, so that they hung above the water, the transmission was perfect. If both wires were allowed to hang, so that the bend came in contact with the water, then the sound was very feeble, although perfectly distinct, just as though the speakers were at a great distance. Again, if both wires were allowed to dip in the middle several metres into the water, it was still possible to hear that someone was speaking, although it was

* From the *Elektrotechnische Zeitschrift*

Digitized by Google

impossible to dis inguish the words. When half the length of the wires, about 75 metres, dipped into the water, it was impossible to hear.

Earth was formed here as before, the iron wire being at one time close to the water's edge, and then further away in a raised part of the ground.

In all these experiments there was no discernable difference between the wires.

In the tests at the railway, Hughes and Morse instruments, as well as buzzers, were used, but in all cases no difference in the wires was noticed.

EXPERIMENTS B.

In order to make the experiments complete a field was chosen which allowed of from 2 to 3 kilometres of wire being laid without any obstruction. This plot of ground is disturbed by no traffic, and the soil is a damp heavy clay. On one side, a stream runs through it. At point A in Fig. 2 a wooden shed was erected; this served as one point to speak from. The earth here consisted partly of a connection to the water mains running under the Zehntstrasse, and partly of a coil of copper wire, let down through an air shaft into the overflow water pipe from the ironworks. At point B a tent was erected, and was used as the second speaking point. The earth here was a large zinc plate soldered to a copper wire and sunk in the stream called the Faulbach. Between points A and B the wire to be tested was laid serpentine fashion in a stubble field and a turnip field. The double-metal wire under examination, of 0·6mm. diameter, was exactly 2½ kilometres in length. All tests were made with this length of wire for all the different wires under examination. Between A and B was laid a direct line of insulated wire to allow of the necessary communications. The apparatus employed was that used by the Post Office for town telephones with dry cells.

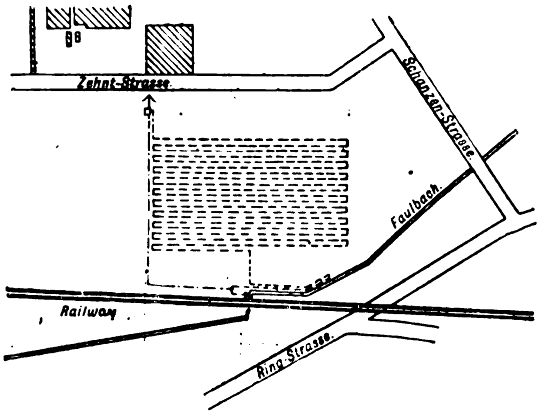

FIG. 2.— — —·—· Insulated Wire. — — — Experimental Wire.

Experiment 1.—A double-metal wire was laid between A and B. In order to keep the wires in their places on the open field, and to provide a means of connection between the wire and damp earth, a number of iron wire staples were driven over the wire and into the ground. Intelligible speech between A and B was impossible. The staples were then removed, but still the result was the same. The portable apparatus at B was then removed to 1 kilometre length of wire from A. (The lengths of 1 kilometre and 2 kilometres were marked by posts driven into the ground.) It was immediately found possible to understand everything. B was then removed to 2 kilometres from A. Here, likewise, speech was possible.

With perfect intelligibility at 1 kilometre and 2 kilometres from A, how was it that only ½ kilometre more should render it impossible to hear anything? This required examination. The last ½ kilometres of wire up to the stream was then carefully examined, when it was found that in this length one of the staples had been left. On removing it speech was possible through the whole 2½ kilometres.

It was then decided to sink a loop of the wire into the Faulbach metre by metre. The very moment the first piece touched the water the loudness of the sound decreased considerably, as if the speakers were at a great distance. Intelligibility, however, remained perfect, although the sound grew weaker as more of the wire was put into the stream, until 4 metres of the wire was in the water, when other noises arose. When 5 metres were in the water intelligible speech became impossible. It had rained hard the day and night before the experiment, so that the ground was completely soaked.

Experiment 2.—Instead of the double-metal wire of 0·6mm. diameter, 2½ kilometres of a double-bronze wire of the same size was laid between A and B, exactly in the same way as in Experiment 1. Speech was perfectly intelligible when 28 metres of the double-bronze wire was in water; numbers spoken could still be understood. When more than 28 metres was in the strength, speech was no longer intelligible.

Experiment 3.—Between A and B was laid 2½ kilometres of pure copper wire of 0·45mm. diameter. Intelligibility was first rate, and the loudness apparently still better than in Experiments 1 and 2. When 50 metres of the wire were laid in water numbers counted could still be heard. The same observation was made in experiments 2 and 3 as in No. 1—namely, that the moment the wire touched the water the loudness diminished considerably. Also, the loudness decreased gradually as more wire was laid in the water.

In Experiments 2 and 3 the weather was continuously rainy, and during the test with the double-bronze wire it poured. In spite of this, intelligibility remained good.

The resistance of the wires employed in Experiments 1, 2 and 3 was about the same in all cases, namely:—

1. 2½ kilometre double-metal wire of 0·6mm. diameter, 270 Siemens units.
2. 2½ kilometre double-bronze wire of 0·6mm. diameter, 261·25 Siemens units.
3. 2½ kilometre copper wire of 0·45mm. diameter, 280 Siemens units.

It was now decided to make tests with wires of much smaller resistance, and two wires used by the Post Office for telephonic purposes were chosen—a copper wire, 4mm. in diameter, and a galvanised iron wire, 3mm. in diameter (a bronze wire 4mm. diameter was not available). The resistances of these wires were as follows:—

4. 2½ kilometre copper wire of 4mm. diameter, 3·75 Siemens units.
5. 2½ kilometre galvanised iron wire, 3mm. diameter, 45 Siemens units.

Experiment 4.—The 2½ kilometre of 4mm. copper wire was connected up between points A and B. There was perfect intelligibility, but the loudness of the sound was much less than in Experiments 1 to 3. When 50 metres of the wire were in water only the faintest sound of the numbers spoken into the telephone was audible.

Experiment 5.—The 2½ kilometre of the galvanised 3mm. iron wire was connected up between A and B. Speech was perfectly intelligible, and the loudness a little better than in Experiment 4, but undoubtedly less than in Experiment 1 and 2. When 5 metres of the wire were in water the result was the same as in Experiment 4.

In Experiments 4 and 5 the weather was fine, but the ground was soaked with rain.

It was only to be expected that the heavy wires would, when lying on the damp earth, give a worse result than the lighter wires, although they would have a better conductivity. This is accounted for by their sinking into the ground, and so presenting opportunities for earth leakage.

In order to test this another experiment was made with a light galvanised 0·2mm. iron wire. The resistance of 2½ kilometres of this was 11,925 Siemens units. This resistance was, therefore, about 44 times that used in Experiments 1 to 3, about 3,180 times that used in Experiment 4, and 265 times that used in Experiment 5.

Experiment 6.—The 2½ kilometre of galvanised 0·2mm. iron wire was connected up between points A and B. The results were very good, and without doubt as good as in Experiments 1 to 3. When 50 metres of wire were in water one could just make out the numbers counted.

In all the tests secondary disturbances occurred from time to time when the wires were in the water. This was found to be due to the acid and chemicals in the water coming from the iron works, which acted upon the wires. Experiment 1, with the double-metal wire, being repeated when the works were stopped, showed that when 50 metres were in water one could still catch the numbers counted. There can be no doubt that if Experiment 2, with the double-bronze wire had been repeated, a similar result would have been obtained.

The results obtained do not show that the double-metal wires are any more valuable than the pure copper wire, but that the distance to which telephonic transmission by bare wires laid upon the earth is possible depends mainly upon the size and weight of the wires, presuming all the conditions are similar.

AN ELECTRIC MINING PLANT.*

BY T. W. SPRAGUE.

A few miles from Pittsburg, at a station on the P. C. and Y. Railway called Hazeltine, is the largest electric power plant for coal mining purposes in the United States, and one of the largest in the world. It is installed to operate No. 2 and No. 3 mines of the Essen Coal Company.

* Abstract from the *Engineering and Mining Journal* of New York.

Digitized by Google

Mr. Dysart, the general manager, made a thorough investigation of coal mining machinery plants, and came to the conclusion that where trouble developed with such plants it was nearly always traceable to insufficient power. Accordingly it was decided in laying out this plant to allow an ample margin of initial power.

The power house itself is excellent in material and construction, and in its general design and arrangement. It is a building 130ft. long by 56ft. wide, steel frame with corrugated iron covering. It is set on a 15in. brick foundation, and the ceiling of the dynamo and engine room is sheathed to prevent trouble from the moisture of condensation. The west end of the building contains four Russell tubular boilers, each 60in. in diameter and 18ft. long, and containing 64 tubes 3½in. in diameter. The four are set with full flush fronts, in batteries of two each, but each boiler has its independent firebox and smoke stack, the latter 60ft. high and 32in. in diameter. Each boiler has its independent feed pipe, there being one feed pump for each battery, as well as an injector for each. The injector piping is so arranged that any boiler may be fed by either injector. The injectors are of the "World" type, and the feed pumps are the Hall duplex, 8in. × 5in. × 10in. each. One Cochrane feed-water heater is installed, sufficient in size to supply all four boilers simultaneously. The boiler room extends along nearly 50ft. of the length of the building, occupying the full width. The boilers are set with sufficient space in front for a coal storage supply, coal being thrown in directly from cars on a spur track running parallel with, and close to, the building, and leaving a wide space behind them for the feed pumps, feed-water heater, &c., which are reached through a passageway between the two batteries. In the space behind the boilers is also a pump furnished by the Hall Steam Pump Company for deep well work. The water supply, or a part of it, at present, comes from these wells, one 129ft. deep, one 160ft., and one 180ft. The water is raised on the compressed air system, the pump or compressor being a tandem machine with an 8in. stroke. The water is pumped into two boilers, 3ft. × 22ft., which are used as supply tanks, being placed about 16ft. above the feed pumps. They also serve as settling tanks, and give sufficient head to fill the boilers when no steam is available.

The engine room, which occupies the central portion of the building through its full width, is 63ft. long. It contains three automatic Corliss engines, with cylinders 17in. × 24in., running at a speed of 153 revolutions per minute. They are set on brick foundations, and have 10ft. flywheels. With the steam pressure usually carried, 90lb. to 100lb., these engines will develop something over 200 H.P. each. They drive three 150-kilowatt bi-polar generators of the "Independent" mining type, wound for 275 volts, and running at 510 revolutions per minute. These 200 H.P. generators are probably the largest bi-polar machines in use to-day. They are compound-wound, and provided with self-oiling bearings, ventilated armatures and other improvements. Space is left for a fourth unit of the same size, which may be added when the work is further extended underground. The engines are set at 30ft. centres from the generators, and 18in. double endless belts are used.

The station instruments are mounted on a marble switchboard, furnished by the Link Belt Machinery Company, which Company took the contract for the entire plant, delivered and erected. The switchboard carries two Westinghouse circuit breakers, three Weston round-pattern ammeters, one voltmeter of the same make, together with the field rheostats and usual switches. Wurts's lightning arresters are placed in each of the two mains leading to the two mines, and also at the bank mouths. One set of arresters is also placed on the long stretch of feeders between the power house and No. 2 mine. The trolley line running outside between the two mines is independently controlled by a single-pole switch in the power house. This stretch is comparatively little used, and is normally "dead."

The remainder of the power-house building is divided into three rooms, a blacksmith and machine shop, a locomotive house and a store room, containing a lathe and some other power tools. The locomotive room is large enough to hold on its two spur tracks the two 80 H.P. locomotives now in use. It is provided with pits for getting at the under parts of the machines and an overhead crane for lifting heavy parts.

The electric power generated is used at present for coal under cutting, haulage and lighting. The plant was started in June and is not yet in complete operation. It is intended to run 16 under cutters, all of the "Independent" chain type; two 80 H.P. locomotives, one in each mine, for the main haulage work (mules being employed to do the gathering), and to light the tipples, power house and underground workings as may be necessary.

The coal cutter is driven by a 20 H.P. "Independent" motor wound for 220 to 250 volts, having but one field coil. The machine is 2ft. high, 2ft. 4in. wide, and 10ft. 5in. long when closed. It cuts to a depth of 5ft., making the cut 3ft. 6in. wide and 3½in. high. The frames of the machine are made of wrought iron and steel. The chain is cast steel, as are the sockets and socket pieces. The straps are drop forged and machinery steel pins are used for putting chain together. Cast iron is not used in any part subject to strain. The motor is well protected, except that its commutator and brushes are exposed. This is claimed to be an advantage, but would seem to increase the risk of damage by mechanical injury to a rather sensitive part of the machine. The control of the machine is easily accomplished by the movement of a lever through 180deg. By this means the cutter may be fed forward, stopped feeding, or reversed without stopping the motor. Another good feature is an automatic stop on the withdrawal. Trucks are provided for transporting the machine from room to room.

The section through the vein in which these machines are working shows a little over 5ft. of practically clean coal underlaid by limestone and capped by 10in. of draw slate. On top of this again is 24in. of coal, capped by 22in. more of slate. The cutters are at present working in the bottom of the seam, and the 24in. of coal above the first layer of draw slate forms the roof. This has fallen down or been taken down on a large part of the main haulage ways, but is kept for the roof otherwise.

The power house is located near the bank mouth of No. 3 mine, about 1,400ft. north-west from the bank mouth of No. 2 mine. Later on another opening situated beyond No. 3 will very probably be equipped electrically, hence the placing of the power house in what will be a central location as the work progresses.

The locomotives, 42in. gauge, are single-motor, four-wheeled machines of the "Independent" type. They run under load at about eight miles per hour, exerting nearly 4,000lb. draw-bar pull, and are each capable of hauling 1,200 tons run-of-mine coal per day of 9 hours from the gathering points to the bottom of the slopes in their respective mines. These distances are, in No. 2 mine, 2,000ft., and in No. 3, 3,300ft. The ultimate length of the main haul by the electric locomotive in No. 2 will be 5,300ft., and 8,500ft. in No. 3.

In both mines mules will be employed for the present in gathering trips and distributing empties, and the locomotives deliver the loaded trips at the bottoms of inclines, from which a drum hoist and cable brings them to the tipples. This elevation of the coal is necessary to obtain proper tipple facilities above the level of the railroad, the seam lying some distance below this level.

The coal cutters are evenly divided between No. 2 and No. 3 mines, there being eight in each. In No. 2 mine their average distance from the bank mouth is 2,000ft., making the distance from the power house to the machines 3,400ft. In No. 3 mine the distance to centre of machine distribution is over 4,000ft. At the present time in No. 3 mine seven cutters are at work, four of which run 10 hours per day, the remaining three working double shift. In No. 2 mine, two cutters are running 10 hours per day, two, 15 hours, and a fifth, 20 hours.

The trolley wire is everywhere No. 00 wire, held by special "Independent" mine insulators. The feed wire for coal-cutting machinery is principally No. 0000, while some of the side entry and all the room wiring is No. 3, all bare copper. In No. 2 mine there is installed 14,500ft. of No. 0000, 4,000ft. of No. 00, 1,000ft. of No. 1, 36,400ft. of No. 3, and 2,156 of No. 8 (tie wire), all bare copper wire, while No. 3 mine contains 14,360ft. No. 0000, 8,850ft. No. 00, 500ft. No. 1, 36,000ft. No. 3, and 2,500ft. No. 8, all bare copper. The only insulated wire used is in the leads to and from the switchboard and about the tipples and station, where lights are used. A ground return is used throughout, the coal cutters being operated on the grounded circuit. The rails are all 40lb. per yard, with fish-plates heavily bonded and cross-bonded at suitable intervals. The return is reinforced from the bank mouths to the power house by three No. 0000 aerial wires from each.

The lighting of this plant is an especial feature. In each tipple and at all switches, &c., in the mine where a light is advisable, the special "Independent" mining arc light has been placed.

In and about the power house, shops, &c., 50 incandescent lamps of 16 c.p. each furnish illumination, run three in series. The locomotives are furnished with arc headlights with powerful reflectors.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September 28, 1895.*

Electricity on Steam Railways.—During the past few weeks a number of tests of the electric locomotive now in use on the Baltimore tunnel road have been made, all of which have resulted very successfully. Much interest has been taken by steam railway men in the results reached at Baltimore and on the Nantasket road, and this has probably been the origin of several recent announcements concerning the introduction of electric power on steam roads. The Illinois Central Railway proposes to use electric locomotives on its terminal lines and

Digitized by Google

short branches, and eventually for passenger traffic on all of its interurban lines in the vicinity of Chicago.

Phase Transformers.—At the September meeting of the American Institute of Electrical Engineers, on Wednesday, Mr. Charles S. Bradley read a Paper on "Phasing Transformers" for obtaining two and three-phased currents from a single alternating current. The principle consists in the employment of capacities and inductances, the idea having been reduced to a very practical shape. The parts of the apparatus consist of a condenser and of a transformer having two distinct primary windings. One of these windings is as in the usual transformer, one end being connected with the source of current, and the other leading to the middle of the second or compound transformer winding; one end of the compound winding is connected to line and the other to a condenser, the other terminal of the latter being connected to line. This disposition produces a difference of phase between the split currents flowing in the two primaries of the transformer, and the secondaries are so arranged as to produce three-phased currents by a method which seems to be the same as that devised by Mr. Scott. Mr. Bradley favours the use of three-phase motors with his transformers, for the reason that he thinks that type of induction motor gives better results than the two-phase type. He states that a condenser such as he has designed for use with his phase transformers occupies a space of a cube of 4in. on each side for a ½ H.P. motor, and will stand 3,000 volts. Mr. Bradley also described a three-phase motor of his design, which was employed in the lecture room to illustrate his Paper. The armature consists of practically two armatures end to end upon the same shaft, one having a low resistance winding and the other a comparatively high resistance; the field is placed over the high resistance for starting, and is shifted by means of a lever over the low resistance when the motor has nearly attained speed. In the discussion of the Paper Dr. Duncan pointed out that with such an arrangement the difference of phase at light load would be very small, which Mr. Bradley said was true. Dr. Hutchinson thought that the principle of the transformer, as far as transforming two and three phases was concerned, was identical in principle with the arrangement of Mr. Scott.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the recent correspondence on the subject of magnetic units few practical engineers were found to favour any alteration or addition to the accepted system of electric and magnetic units. Whilst agreeing that those who are daily engaged in practical calculations do not feel any supreme need for new units or names, may I express my belief in the ultimate and perhaps not far distant victory of Mr. Heaviside's "radical cure"? In a letter published in *Nature*, July 28, 1892, Mr. Heaviside advocated two reforms—viz., (1) the elimination of 4π from all cases which have no immediate reference to circles or spheres, and (2) the use of a single multiplier, such as 10^8, in passing from absolute to practical units. While the second of these appears to me of doubtful advantage in our present practical state (since it involves the alteration of the watt), the case of the first stands on a different footing; it is not a question of mere convenience, but of whether its adoption leads to truer views and a greater logical simplicity. If it does, should we not be confident that our successors will reap the reward of our self-denying efforts in the more rapid advancement of our science? Probably few will dispute that on scientific and logical grounds Mr. Heaviside has entirely the best of the argument; in fact, nothing requires to be added to the reasons adduced by the author in favour of his scheme. As a practical measure, however, there are two grounds on which at present it is rejected.

In the first place, how are we to know that in a few years the whole system of units will not again have to be cast into the melting pot and further refined? To this there can be no categorical answer; the question of sufficient finality must be left for decision to our best thinkers, who have the clearest insight into the future course of electrical science.

The second objection is the great difficulty of altering the volt, ampere and ohm as the legalised basis of a most important industry. It is this objection which seems to require fuller discussion, and to admit of an a swer, for is it not the case that we are apt to overrate the difficulty of the change? Of course, the starting point must be international agreement; but, this secured, how would the reform work itself out? The rational system could at once form the basis of every new text-book, and be assimilated by the students of our technical institutes. It would then spread to the instrument factory; ammeters and voltmeters calibrated in the new units would be in request for laboratories, and thence would gradually spread to central stations and workshops. Lastly, it would reach the "final consumer" in the shape of the engineer buying a dynamo or motor, or the householder replenishing his stock of lamps. In the transition stage glow lamps can easily be marked with both the old and new voltage. Probably the majority of purchasers of dynamos and motors gauge them by their horse-power of input or output, or by their capacity in number of lights, seldom by their volts and amperes; and if the second reform of Mr. Heaviside be vetoed, the old and new watt or the rated output of any machine in kilowatts remain unchanged. Parliamentary sanction would in the end complete the change, and the old system of units would be relegated to the limbo of dogmas and superstitions which we have outgrown. Is, then, the reform of such an heroic nature that we need abandon it as an Utopian dream, less likely to be realised than even the overthrow of the yard, gallon and pound?—Yours, &c.,

October 1, 1895. C. C. HAWKINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with the recent discussion in *The Electrician* on magnetic units, the following may be of some little interest.

If m and m', q and q' be point charges of magnetism and electricity respectively, and μ and k the magnetic and electric constants of the medium, the forces between the charges when at distances r apart are

$$F = \frac{1}{\mu} \cdot \frac{m m'}{r^2}, \qquad F = \frac{1}{k} \cdot \frac{q q'}{r^2}.$$

In these equations, μ and k are undirected or scalar quantities if the medium is isotropic; the products $m m'$ and $q q'$ are also scalar, whatever the nature of m and q may be, and r^2 is scalar. The right-hand member of each equation is, therefore, a *scalar*; but the left-hand member is a *vector*, since F is directed. We thus see that the right-hand member is incomplete as it stands, since it fails to specify or to indicate the directional nature of the vector on the left.

This incompleteness would seem to arise from the fact that 4π, the surface of unit sphere, is omitted on the right. Thus, proceeding according to Mr. Heaviside, if H and E be the intensities of the fields produced by m and q at a distance r from either charge, we have

$$H = \frac{1}{\mu} \cdot \frac{m}{4\pi r^2}, \qquad E = \frac{1}{k} \cdot \frac{q}{4\pi r^2}.$$

The right-hand members of these equations correctly specify the nature of the vectors H and E on the left. They are vectors of the "flux" type, the field due to m or q at any point distant r away being normal to the element of the surface $4\pi r^2$ taken at that point, and estimated with respect to it. In other words, every element of the surface $4\pi r^2$ which appears on the right is directed along the radius from the centre, and it is the presence of this factor in the relation that endows it with its true directional character.

Since the mechanical forces experienced by m' and q' when placed in fields of intensities H and E are m' H and q' E respectively, we get for the fundamental equations

$$F = \frac{1}{\mu} \cdot \frac{m m'}{4\pi r^2}, \qquad F = \frac{1}{k} \cdot \frac{q q'}{4\pi r^2},$$

equations which are now *directionally* true.

Digitized by Google

This, in addition to other considerations, would seem to point to the superior consistency and rationality of the system of units proposed by Mr. Heaviside.—Yours, &c.,

W. Williams.

Royal College of Science, London, Oct. 7, 1895.

"INERT" IRON.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have to record an experience which occurred here to-day, and it may prove of service to others if published. All the arrangements of my installation are autom tic, and no failure has been observed during the past eight years—*i.e.*, since the start of this method.

To-day the engine driver could not commence charging, the cut-outs "went off" with great violence. I made a careful examination all round, and nothing wrong could be discovered. The manner in which the cut-outs "went" indicated a "reversal." I therefore tested the dynamo, which was to be used, more closely, and found the iron of the magnets *absolutely* inert; hence no E.M.F. could be produced when set in motion. Such an occurrence is very remarkable, the iron, very soft, weighing probably over one ton. This dynamo is one of Crompton's, and was started January, 1886. It is a beautiful machine, having done good work, and showing no sign of wear. Of course, the iron was soon magnetised by turning on the accumulators when the brushes were raised. Whether magnetic earth storms were the cause of the trouble or not, it would be interesting to know; but as such a failure is always possible, though rare, with efficient dynamos, I would suggest a simple remedy. A flat plate of hard steel placed at the side of the iron core would be an effectual cure, and not alter the virtues of the apparatus.—Yours, &c., David Salomons.

[If the machine be shunt wound it is possible the "inert" iron effect was due to starting on such a low resistance that the shunt-coil was practically short-circuited. At any rate we prefer this hypothesis to that of "magnetic earth storms."—Ed. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions can now be sent in.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "The Electrician" Series can be obtained of the Booksellers or direct from the Publishing Offices:—

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A Sheet Table showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d.

A Sheet Table giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d.

Tenders Invited.—Tenders are being invited by the Postmaster-General for (*a*) the supply of red fir telegraph poles, and (*b*) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot. Forms of tenders may be obtained on application to Charles E. Stuart, Controller of Stores, General Post Office, E.C., and tenders must be in by noon on Monday, the 28th inst. Further particulars appear in our advertisement columns.

——— Tenders for the supply of a quantity of telegraph cable and copper wire, in two lots, are being invited by the Direction-Générale des Chemins de Fer, Postes et des Telegraphes, Brussels. Tenders by the 16th instant.

——— Tenders are required for the wiring of the Waverley Market, Edinburgh. Tenders to Mr. Thomas Hunter, W.S., Town Clerk, City-chambers, Edinburgh, by tomorrow, Saturday.

——— The Director of Public Works, Madrid, invites tenders for the concession for the construction and working of a tramway from Madrid to Colmevar Viejo, Chamartin and Rosa. Tenders by the 15th prox. to the Direccion General de Obras Publicas, Madrid.

——— The Municipal Authorities of Loria are inviting tenders for a 20-years concession for the electric lighting of the public streets. Tenders to be sent to the Ayuntamiento de Loria, Spain, by the 15th inst.

——— The Dutch Colonial Minister requires tenders for the supply of cast and rolled iron, iron and steel wire, white sheets, zinc, tools, &c. Tenders to the Ministry for the Colonies, The Hague, by the 16th instant.

——— Tenders are required for the installation of the electric light at the Poor Law Offices, Mawdsley-street, Bolton. Tenders must be sent in to the clerk (Mr. Simpson Cooper) not later than 12 o'clock on Tuesday next, the 15th inst.

——— The Saltash Town Council invite tenders for lighting the district by electricity, gas, or otherwise, from the 4th January next. Particulars of the Chairman of the Works Committee, Mr. W. Alford, 3, Springfield-terrace, Saltash, to whom tenders should be sent not later than Saturday, the 25th inst.

Tenders Accepted.—The Farnworth and Kearsley Co-operative Society have accepted the tender of Mr. R. S. Blackburn, of Hebden Bridge, for putting their central premises in Market-street, Farnworth, in telephonic communication with their outlying branches.

——— We learn that the tender of Messrs. B. Verity and Sons, of London and Manchester, has been accepted by the Blackpool Town Council for the wiring, &c., of the Town Hall.

——— The Sunderland Town Council have accepted the tender of the Electric Construction Company (Limited) for the supply of transformers for their electricity works.

——— The South Molton Shirt and Collar Manufacturing Company (Limited) have received twenty tenders for supplying generating plant, wiring their premises for the electric light, &c. The figures varied from £715 to £198, and the tender of Messrs. Newton and Hawkins, of Taunton, which amounted to £282, has been accepted.

——— The Oswestry Town Council have accepted the tender of Mr. Reakes, Shrewsbury, for wiring the Cross Market for the electric light for the sum of £62.

——— The Asylums Committee of the Portsmouth Town Council have accepted the tender of Mr. J. Southey, of King's-road, Southsea, for wiring the building for the electric light.

Tenders Received.—The Bedford Urban Sanitary Authority have received the following tenders for the supply and delivery of 200 cast-iron lamp columns, carriers, and globes:—

	Cast-iron Tops.			Sheet-copper Tops.		
Bradley, W., Brighouse (*accepted*)	£449	0	0	£519	0	0
Mackenzie Bros., Edinburgh	—			1,350	0	0
Smith (Geo.) and Co., Glasgow	1,050	0	0	1,050	0	0
Hart, Son, Peard and Co., Birmingham	960	0	0	—		
Goddard, Massey and Warner, Nottingham	850	0	0	910	0	0
Ashmore, Benson, Pease and Co., Stockton	—			739	0	0
Lloyd's Works, Abercarn	—			563	6	8
Macfarlane and Co., Glasgow	811	13	4	830	0	0
Pontifex and Co., London	700	0	0	950	0	0
Kilpin and Billson, Bedford	653	0	0	765	0	0
Newton, Chambers and Co., Sheffield	650	0	0	800	0	0
Sharpe and Co., Lancaster	632	0	0	782	0	0
Cochrane and Co., Dudley	—			650	0	0
Ulverston Shutter and Lift Co., Ulverston	625	0	0	—		
Alloa Iron Company, Alloa	620	0	0	715	0	0
Phœnix Foundry Company, Derby	579	0	0	—		
Hollam and Co., London	540	0	0	660	0	0

Digitized by Google

TENDERS RECEIVED.—The following tenders have been received for the installation of the electric light at the New Theatre, Cambridge :—

Rashleigh, Phipps and Co., London	£893
Strode and Co., London	555
Crampton (W. J.) and Co., Cambridge	479
Wenham and Waters, London	449
Baily, Grundy and Barrett, Cambridge	330

SALE BY AUCTION.—From our advertisement columns this week it will be seen that Messrs. Wheatley Kirk, Price and Goulty, in compliance with instructions from Mr. D. Ellis, the receiver and manager in the liquidation of Poole and White (Limited), will sell by public auction at an early date that Company's electrical engineering works, together with the valuable and modern fixed and loose plant, &c. Plans and particulars can shortly be obtained gratis from Messrs. Steavenson and Couldwell, 93, Gracechurch-street, E.C., or from the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-chambers, Albert-square, Manchester.

PLANT FOR SALE.—Particulars are given in our advertisement columns of some plant which Messrs. Henry Lea and Thornbery, 38, Bennett's-hill, Birmingham, have for sale. The plant includes four gas engines, three Elwell-Parker dynamos, switchboard and instruments, shafting, pulleys, leather belting, &c.

——— Our advertisement columns contain particulars of some plant for which the Brighton Grand Hotel Company invite tenders. The plant includes three boilers, one 25-kilowatt "Oerlikon" dynamo, one 13-kilowatt "Victoria" dynamo, a battery of accumulators, switchboards, instruments, &c.

APPOINTMENT.—The Hull Town Council have appointed Mr. A. S. Barnard electrical engineer at their electricity works. The salary is £250 per annum. Mr. Barnard has been in the service of the Lancaster Corporation as borough electrical engineer since 1893.

APPOINTMENT VACANT.—At their meeting on the 29th inst. the Dundalk Town Commissioners notify that they will appoint an electrical engineer for the purpose of reporting on the electric lighting question.

REMOVALS.—The Epstein Accumulator Company (Limited) inform us that owing to the great increase in their business they have been compelled to remove their head offices to more commodious premises at Victoria Mansions, 28, Victoria-street, Westminster, S.W., where all communications should in future be addressed.

——— MM. E. H. Cadiot et Cie., electrical engineers and agents, inform us that they have removed their offices to 12, Rue St. Georges, Paris, where future correspondence should be addressed.

——— M. Lucien Espir notifies that, owing to increase of business, he has been compelled to remove his offices and show rooms to 11 bis, Rue de Maubeuge, Paris.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. C. H. Smeeton and H. Page, hitherto carrying on business as electrical engineers, under the style of Smeeton and Page, at 63, Queen Victoria-street, London, E.C., have dissolved partnership.

——— The partnership business of electrical engineers hitherto carried on by Messrs. F. Woolstone and W. Nottingham, under the style of Woolstone and Nottingham, Leeds, has been dissolved.

——— Notice is given that the partnership business of engineers and merchants hitherto carried on under the style of Bagshawe Bros. and Co., at Upper Thames-street, London, E.C., and at Paris, has been dissolved. Messrs. W. H. W. Bagshawe, of London, and A. Bagshawe, of Paris, retire.

BANKRUPTCIES.—The adjourned meeting of creditors under the failure of Ronald A. Scott (Limited), lately carrying on business as electrical engineers at Acton Hill, W., was held at the offices of the Official Receiver for the Brentford district, Temple-avenue, E.C., under the presidency of the Senior Official Receiver (Mr. Cecil Mercer), yesterday. The statement of affairs as regards creditors showed gross liabilities amounting to £5,967. 10s. 4d., of which £927. 8s. 8d. was due to unsecured creditors. The assets, consisting of stock-in-trade, machinery, &c., were estimated to produce £1,000. The statement of affairs as regards contributories showed total liabilities, which are expected to rank for dividend, amounting to £5,934. 8s. 8d., and assets *nil*. The Official Receiver reported that the winding-up order was made on July 30 last, and a statement of affairs has been submitted by Mr. Ronald A. Scott, the late manager of the Company. The Company was formed in June, 1894, to purchase the business, goodwill, &c., of Ronald A. Scott, of Acton Hill, W., and to carry on the business of electricians, engineers, electrical engineers, and general contractors. The nominal capital was £10,000, in 10,000 £1 shares. No allotment took place, except the £1 paid by each of the seven signatories to the Memorandum and Articles of Association. No other shares were issued to the public, and Mr. Scott was practically the Company. As the consideration for the sale of the business £5,000 fully paid-up debentures were allotted, to Mr. Scott and he subsequently transferred these debentures to certain creditors. On December 6th last, on the application of the debenture-holders, Mr. P. T. Travers, of Ryder-street, S.W., was appointed receiver, and he carried on the business until May last, since which time the business has been practically closed. The cause of failure is attributed to want of capital. Assuming that the validity of the debentures cannot be impeached, the value of the business and other assets is of no practical interest to the creditors, as there will not be sufficient to pay the debenture-holders. Mr. Scott was questioned with regard to certain French patents, and he stated that these patents had been worked by a Mr. Starkey on royalty. He could not remember the terms of the agreement, but he thought Mr. Starkey had power to return the machines, and give up the work at any time. He also thought the debenture-holders had a prior claim over those patents, as they were included amongst the assets of the Company when it was formed. The debtor further referred to his advertising patent, and said that owing to the outcry raised against throwing advertisements on Nelson's column and the National Gallery, Trafalgar-square, he was compelled to give up experimenting under the patent. Eventually the estate was left in the hands of the Official Receiver. A list of the creditors under this failure has been published, and we give below the principal of these :

	£	s.	d.
Wells Bros. (Sandiacre)	£145	0	0
Wilkes, Sons and Mapplebeck (Birmingham)	78	0	4
Nitsche and Gunther (London)	68	8	0
Pattison and Co. (Leicester)	42	0	0
Highton and Co. (London)	38	0	4
Schultz and Co. (London)	36	5	3
W. T. Glover and Co. (Salford)	35	0	0
Williams, Foster and Co. (London)	23	10	6
Sankey and Sons (Bilston)	23	6	7
Spencer and Sons (Newcastle)	21	13	6
Irvine and Sellars (Preston)	20	6	6
Colver Bros. (Sheffield)	17	19	5
Mosses and Mitchell (London)	16	9	2
C. Atkins and Nisbet (London)	15	8	5

BANKRUPTCIES.—The statutory meeting of creditors under the bankruptcy of D. J. Whatmough, lately carrying on business as an electrical engineer at the Market Place, Oldham, under the styles of D. J. Whatmough, and J. and P. Dyer, and formerly as W. Mason, took place at the offices of the Official Receiver, Oldham, on the 3rd inst. The district Official Receiver presided, and after some discussion Mr. J. Jones, accountant (Messrs. Mountain, Jones and Co.), Manchester, was appointed to act as trustee, with a committee of inspection.

——— The adjourned public examination of Mr. E. H. Berry, formerly carrying on business as an electrical engineer and contractor at Burnley, took place at the Burnley Bankruptcy Court on the 3rd instant. Mr. Price, who appeared for the trustee, pointed out that the examination had been adjourned once or twice in order that the debtor might furnish an amended statement of accounts, but he had only furnished one similar to the other, except he had put in an item for travelling expenses amounting to £240. The statement was not verified by affidavit, and Mr. Price stated that he found the debtor had omitted various items. He therefore asked that the debtor's examination be adjourned. The bankrupt, in reply, said that he had not understood how the account should be made out, and that he was being misrepresented. Since the first occasion he had taken some trouble to make the account out, but he might have forgotten some items. The examination was adjourned *sine die*.

LIQUIDATIONS.—A petition has been presented by Messrs. C. A. Parsons and Co., of Newcastle and Leeds, for the winding up of the British Steam Generator and Refuse Utilisation Company (Limited), and will be heard on the 30th inst. at the Royal Courts of Justice, Strand, London, W.C. Messrs. Wrensted and Sharp, of Ormond House, Great Trinity-lane, London, E.C. (agents for Messrs. Robinson, Scott and Holmes, of Bradford), are solicitors for the petitioners.

——— At a meeting of the proprietors of the Railway Automatic Electric Syndicate (Limited) on the 19th ult., it was resolved to wind up the Company voluntarily. Mr. John M. Tourtel, of the Depôt, Mill Hill Park Station, Acton, Middlesex, was appointed liquidator.

——— At a meeting on the 25th ult. it was decided that Baird, Thompson and Co. (Limited), heating and ventilating engineers, Charlton Works, Charlton Place, London, N., and Glasgow, be wound up voluntarily. Mr. J. Coop, of the firm of Davies, Tait and Co., 46, Queen Victoria-street, E.C., was appointed liquidator.

——— At a meeting on the 26th ult. it was resolved to wind up voluntarily Hargreaves and Shaw (Limited), electrical and mechanical engineers, Atlas Works, Ashton-under-Lyne. Mr. J. C. Atkins, C.A., Oldham, was appointed liquidator.

Digitized by Google

ELECTRIC LIGHTING SCHEMES INVITED.—The Battersea Vestry offer premiums of £50, £30 and £15 for the best three schemes, reports, designs and estimates for a system of electric lighting for the parish of Battersea. Schemes must be delivered to Mr. W. Marcus Wilkins, the Vestry Clerk, before 12 o'clock (noon) on Thursday, December 12th next. Further particulars are given in our advertisement columns.

ELECTRIC HAIR CURLERS.—Miss Elizabeth L. Banks writes to the *Daily News*, *apropos* of the "Iona" disaster, calling attention to the danger of the ordinary hair curler when used on board ship, and suggesting that liners should be fitted with electric hair curlers.

AGENCY.—Mr. F. W. Ostermann, of 27, Leadenhall-street, E.C., has been appointed sole British agent for the Boeddinghaus double-spiralled plug. A description of this screw plug appeared in our issue of July 26th last.

ELECTROTHERM.—We have received of Messrs. Witty and Wyatt (Limited) their small catalogue of an electric heating and warming pad, which goes by the name of "Electrotherm." It consists of a flexible sheet or pad composed of asbestos, with embedded wires, which, when connected by a length of flexible wire and a socket, to an electric light circuit, develops a uniform and constant temperature. There is in the catalogue a list of ailments from which the electrotherm is designed to afford relief; and, in the event of the purchaser or his friends not suffering from any one or more of these, the instrument may be used as a convenient foot-warmer. Messrs. Witty and Wyatt are the sole European and colonial agents of the H. W. Johns' Manufacturing Company, of New York.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—We have just received a copy of the new catalogue of standard size continuous current dynamos issued by this Company. The tables in this publication state the output, speed, price, &c., of the machines, for various standard voltages, ranging from 50 to 135 volts. There are also a list of prices for accessories, and a table of the dimensions of the standard machines.

CATALOGUES.—The United Asbestos Company (Limited), Dock House, Billiter-street, E.C., forward us a copy of their new illustrated catalogue. Particulars are given of the Company's "Victor" jointing materials, which, it is stated, are now used in 120 ships of H.M. Navy, in about 500 merchant steamers and by many engineering firms. Details are given of the "Salamander" joints, the "A" brand of which is recommended for high pressures, and for wet steam, water and other joints, while the "B" brand is recommended for dry steam. The Company also draw special attention to their new patent "Salamander" embossed decorations. These decorations are a novel adaptation of asbestos, and the Company claim that they are very efficacious in preventing the inception or spread of fire wherever used, either in saloons of vessels or in buildings. Particulars and prices are also given of the Company's fireproof paints, non-conducting coverings, cements, &c., pipe and flange jointing materials, "Gladiator" and other packing, belting, "Rubesto" sheeting, tape joints, &c. The catalogue is furnished with an index, is well printed, and is undoubtedly one of the completest of the kind we have seen for some time.——Messrs. C. H. Cathcart and Co., 3, Dorset-buildings, Salisbury-square, E.C., forward us circulars containing prices and particulars of their mill and factory electric light fittings. The firm also send us particulars of their table standards. These standards are suitable for use in office or library, and as the bases are being heavily weighted, are not easily overturned.

ABERDEEN.—At the last meeting of the Town Council a letter was read from the Building Committee of the Free Bon-Accord Church, stating that they had been considering the propriety of lighting the new church on the Viaduct by electricity, and asking if the Council would be prepared to extend their mains so far. The letter was referred to the Gas and Electric Lighting Committee.

ALDERLEY EDGE (CHESHIRE).—At their meeting on Tuesday the District Council considered the question of the purchase of the Council's Provisional Order by Mr. S. V. Clirehugh, consulting engineer, Manchester, who is acting on behalf of a Company about to be formed for the purpose of supplying the district with electric current. The terms of the agreement were discussed at great length, but it was eventually decided to call another meeting of the Council to further consider the question.

BANGOR.—At the meeting of the City Council on Wednesday it was decided, on the recommendation of the Electric Lighting Committee, to apply for a Provisional Order. The Committee also recommended that Mr. F. H. Medhurst be engaged as consulting electrical engineer (provided the Council obtain the necessary powers to proceed with their scheme) at a remuneration of £650; if, however, the Council did not proceed further with the matter, Mr. Medhurst's fee would be £50. This recommendation was also adopted.

BELFAST.—At the last meeting of the Electric Light Committee the electrical engineer (Mr. V. A. H. M'Cowen) submitted his report on the proposed extension of the electric light mains in Arthur-street, Howard-street, College-square North, College-square East and Wellington-place, together with an estimate of the probable cost, and he was authorised to proceed with the work. The tenders recently received by the Committee for the supply of additional engines and dynamos were referred to the engineer for analysis and report.

BLACKBURN.—The Markets Committee's recommendation that the Market House and the Fish Market be lighted by electricity was adopted at the last meeting of the Town Council. The Gas Committee has decided to reduce the charge for electric current for motive-power purposes to 4d. per unit.

BLACKPOOL.—At the meeting of the Town Council on Friday last Councillor Pearson, in presenting the Electric Lighting and Tramways Committee's report, spoke in glowing terms of the great success of their electric light undertaking. He also reported that the Board of Trade had granted a licence to work the Lytham-road tramways, and they had decided to adopt electric traction on the section between the Carriage Drive and the South Shore Railway Station. The minutes were duly approved.

BRADFORD.—At the meeting of the County Council on Tuesday, the Chairman of the Gas and Electricity Committee (Mr. Dixon) presented his statement of the income and expenditure of the Electricity and Gas Departments for the year ended June 30th last. Referring to the Electricity Department, Mr. Dixon said the capital outlay had been £67,111, the income amounted to £6,185, and the expenditure to £3,008, or a gross profit of £3,177. After deducting £2,190. 5s. 9d. for interest and sinking fund, there remained a net profit of £986. He said they were at present renovating their plant, and, owing to certain machinery not having been delivered to time, they were compelled to refuse some customers. In conclusion, Mr. Dixon referred to the progress the Department had already made, and said that, properly managed, there was a great future before their electricity works.

BRIERLEY HILL (STAFFS.).—The District Council are greatly dissatisfied with their present system of gas lighting, and the clerk has been instructed to ascertain the cost of lighting the district by electricity.

BRIGHTON.—At a recent meeting of the Works Committee a letter was received from Mr. Magnus Volk, Managing Director of the Brighton and Rottingdean Seashore Electric Tramroad Company, requesting permission to erect some poles on the foreshore for the purpose of carrying electric wires. The Committee informed Mr. Volk that the Council could not sanction the erection of these overhead electric wires, but would grant permission to lay them underground, subject to the work being approved by the Borough Surveyor. On the motion for the approval of the minutes of the Committee at the last meeting of the Town Council, it was decided to refer the matter back for further consideration.

BRISTOL.—It is announced that the formal opening of the electric tramway between Old Market-street and Kingswood will take place on Monday next.

BUENOS AYRES.—It is reported that an underground electric tramway will shortly be constructed in this city.

BURY.—The Town Council at their last meeting appointed a Committee to consider the question of lighting the town by electricity.

CHELTENHAM.—At each successive meeting of the Town Council the Electric Lighting Committee have to report an increased demand for electric current. According to the statement of Alderman Norman (Chairman of the Electric Lighting Committee) at the last meeting of the Council, the Committee had applications for 4,270 lamps, and 3,040 of these had already been connected up.

DOCK LIGHTING.—The quay wall between the Trafford-road swing bridge and the entrance to the Pomona Docks is to be lighted by electricity. To persons who have to navigate craft after nightfall in this crooked part of the canal, the electric light will be a decided advantage.

DOVER.—At the meeting of the Town Council on Wednesday Mr. G. Fry introduced the question of the construction of a system of electric tramways in the town, and, after considerable discussion, it was decided to apply for Parliamentary powers to carry out the proposal forthwith. The estimated cost of constructing and equipping between three and four miles of tramway, erecting a generating station, &c., was put at £50,000.

DUNDEE.—The accounts of the electricity department of the Town Council for the five months ended September 30th have just been published. The electricity rental for this period amounted to £907. 3s. 4d., an increase of £189. 3s. 4d. as compared with the same period of last year.

ECCLES.—At the meeting of the Town Council on Tuesday last the Electric Lighting Committee presented their report on the tenders recently received by the Council for carrying out the proposed electric lighting scheme of the Council. The scheme was prepared by Mr. S. V. Clirehugh, of Manchester, and provided

Digitized by Google

for the lighting of the whole of the district at present lighted by gas, and also for the supply of current for private lighting. After very careful consideration of the whole of the tenders sent in, the Committee recommended the adoption of the tender of the Manchester Edison-Swan Company, which amounted to £13,792, and the Committee further recommended that application be made to the Local Government Board for sanction to borrow £20,000 for the purpose of carrying out the scheme. Mr. Alderman Kendall moved the adoption of the Committee's report, but Mr. F. Smith moved an amendment that the question be postponed till after the November elections, and after a long discussion the amendment was carried.

EDINBURGH.—At the meeting of the Town Council on Tuesday the Cleaning and Lighting Committee recommended that the Grassmarket and West Bow should be lighted electrically at a cost of £140, and that an arc lamp be erected at the corner of Picardy-place and another at the corner of London-road, at a cost of £40. After some discussion the proposals were referred back to the Committees for further consideration. The Town Council also discussed the bill which is being promoted for the extension of the city boundaries. In the bill is a clause providing for the extension of the present electric lighting area.

ENFIELD (MIDDLESEX).—The Town and Village Electric Light and Power Company have written to the District Council offering to submit a tender for the lighting of the district by electricity. The letter was referred to the General Purposes Committee.

ELECTRIC LIGHTING LOAN.—At the weekly meeting of the London County Council on Tuesday the Finance Committee reported that they had considered an application from the Vestry of Islington for a loan of £5,150 for the purchase of land for electric lighting purposes. The Vestry found it necessary to extend their electric lighting station, and for that purpose purchased certain property in Burnard-place, Eden-grove, adjoining the existing station. The Council's valuer reported that under the exceptional circumstances of the case the price paid was not unreasonable, and the Committee therefore recommended that the loan be granted on condition that it was taken up at once, interest being charged thereon at the rate of £3 per cent. per annum, and the entire sum to be repaid within a period of 53 years. The recommendation was agreed to.

EXHIBITIONS.—The Leeds International Exhibition was opened on Wednesday last. The Exhibition, which was promoted by the General Trades and Industrial Exhibition Company, is being held in the Engineers' Drill Hall, Camp-road, and will remain open until November 1st. There are about 200 exhibitors, and the building will be lighted throughout by electricity, the work of installation having been placed in the hands of Mr. F. J. Borland, electrical engineer, of Leeds; 18 1,000 c.p. arcs and a large number of incandescents will be employed. Power for driving the dynamo is being supplied by Messrs. Robey and Co., the well-known steam engine makers, of Lincoln, who are exhibiting some of their steam and gas engines. Mr. F. J. Borland also exhibits various electrical appliances, and has constructed a short electric railway in the grounds.

——— It is stated that though the time fixed for sending in applications for space in the Industrial Exhibition which is to be held next year in the Treptow Park, Berlin, many applications are still being received by the administration. It has therefore been found necessary to enlarge the original plans, and the principal building, to which a space of 40,000 square metres had originally been allotted, will now cover 53,000 square metres, and some of the subsidiary groups which were intended to form part of the main building will now occupy a separate hall.

FACTORY LIGHTING.—The new co-operative clothing factory at Kettering, which was formally opened on Tuesday last, is lighted throughout by electricity. The installation was carried out by Messrs. Lee and Warren, of Kettering.

FULHAM (LONDON, S.W.).—At the last meeting of the Vestry the Special Electric Lighting Committee reported that they had received answers to the queries they had addressed to the various local authorities who possessed electric lighting powers. Mr. Sayer moved the confirmation of the report, which was, after some discussion, agreed to, as was also a resolution that an electrical expert be employed by the Committee at a cost not exceeding £50.

GODALMING.—The Special Lighting Committee presented their report at the last meeting of the Town Council. The report stated that the Highways, Footways and Lighting Committee had handed over to them the tenders received for the electric lighting of the district. Seventeen schemes had been received, but not one of the firms who tendered would undertake to establish electric lighting works at their own risk. As a result of the consideration of the schemes the Committee had instructed their surveyor to enter into negotiations with Messrs. J. Fowler and Co., Leeds, and to canvass a specified area of the borough with a view to finding out how many lights were likely to be required. They recommended that they be empowered to obtain a Provisional Order, provided the cost did not exceed £250. The Chairman of the Committee (Mr. Girdlestone), in moving the adoption of the report, said it had been found impossible to attempt the lighting of the whole of the borough electrically at first, and they had determined to take a limited area in which the houses were closed together as an experiment. The result of their canvass was fairly satisfactory, and the headmaster of Charterhouse was anxious to have the electric light introduced into the school, and, taking the whole aspect of the case, there was a very general and strong desire for the electric light in the borough. The report was carried unanimously.

GREAT YARMOUTH.—The Town Council have decided to put the Town Hall in telephonic communication with the Sanatorium and the Corporation stables at a cost of £68. 10s. At the last meeting of the Council the surveyor stated that there were at present 5,495 lamps connected up to the electric light mains, and that the profit on the electricity department for the month of September was £88. 5s. 8d., while the profits for the months of August and September amounted to £142. 4s. 7d., which, the surveyor states, just covers the loss on the first seven months' working.

HAMPSTEAD (LONDON, N.W.).—It appears that the Vestry are at present paying interest to the London County Council on their electric lighting and other loans at the rate of 3½ per cent. per annum, and they are naturally anxious to obtain a reduction on this excessive rate. The Finance Committee have, therefore, been commissioned to consider and report on the question of obtaining better terms from the Council.

HANLEY.—On the recommendation of the Parks Sub-Committee the borough surveyor has been instructed to prepare and submit a scheme for lighting the boathouse and lake in Hanley Park by electricity.

ISLINGTON (LONDON, N.).—The Electric Lighting Committee of the Vestry require an additional £25,000 to complete their electric light undertaking. This additional expenditure is partly caused by under-estimates, and the balance is required for the purchase of more property in Eden-grove for extending the generating station.

LAMBETH (LONDON, S.E.).—Although the members of this Vestry have had, during the past two or three years, several discussions on the subject of introducing the electric light into the parish, they do not appear to have made much progress with the matter. At the last sitting Mr. Bennetts moved that a special committee be appointed to collect information, and to consider and report upon the whole question, but the Vestry adjourned without coming to a decision.

LONDON, E.C.—It is stated that arrangements are being made for the introduction of the electric light into the London Commercial Sale Rooms, Mincing-lane, E.C.

MILE END (LONDON, E.)—The Vestry have appointed a Committee to consider the question of lighting the district by electricity.

MONMOUTH.—At the meeting of the Town Council on Monday the Mayor (Councillor W. Honeyfield) stated, in reply to a request for information as to the suggested refuse destructor and electric lighting scheme, that the engineers (Messrs. Bramwell and Harris) had reported that the combined scheme would cost £20,000.

NEW MALDEN (SURREY).—Some time ago the Kingston Corporation suggested to the District Council the advisability of introducing the electric light into the Coombe district, and at the last meeting of the Council the Highways Committee reported that they had fully considered the question, but they recommended that the Kingston Corporation be informed that the suggestion cannot be entertained at present.

NEWPORT (MON.).—The formal opening of the electricity works takes place on Monday next, the 14th inst.

OLDHAM.—At the last meeting of the Electric Lighting Committee it was decided to recommend the Council to adopt the Brighton system of charging for current. The Council have received the formal sanction of the Local Government Board to borrow £15,000 additional for electric lighting purposes, the loan to be repaid in 25 years.

OSWESTRY.—At the last meeting of the Council it was stated that the Oswestry Electric Light Company were prepared to supply current to six 500 c.p. lamps for lighting the Cross Market for £60 per annum. The present gas lighting costs £42. 3s. 6d. The Company's proposal was accepted.

OXFORD.—At the last meeting of the City Council the Streets, Roads and Lighting Committee reported that they had received certain proposals from Mr. J. Hardie McLean, managing engineer of the Oxford Electric Company, for lighting certain portions of the city by electricity. These proposals provided for the erection of 32 arc lamps in some of the principal thoroughfares, and the cost of supplying current would be £688 per annum. Eight were to be all-night lamps, while current would be cut off from the remaining 24 at midnight; but on each of these 24 lamp-posts a double bracket would be placed about half-way up each post, carrying a 32 c.p. incandescent lamp, which would be lighted at midnight. The all-night lamps would cost £26 each per annum, and the combination lamps would cost £20 each. If, however, the Committee considered that two 16 c.p. incandescents

Digitized by Google

would be sufficient for each of the 24 combination lamps, the cost would be reduced to £652 per annum. The Committee recommended that the latter proposal be accepted, and that a contract be entered into for a term of six years with the Company, the contract to be determinable at the end of the first three years at the option of the Corporation. Mr. Kingerlee moved the adoption of the report, and said that about three years ago they lighted a small area of the town by electricity, and the Committee had unanimously decided that it should be continued. The cost of the original scheme was £380 a year. The entire cost of laying down mains and providing and fixing lamp-posts was to be borne by the Company, and the whole of the 32 lamps would be 2,000 c.p. each. These 32 lamps would displace gas lamps of the equivalent of 834 c.p. The matter was discussed at great length, several of the members complaining of the inadequate illuminating power of the existing gas lamps. The report was adopted, with only one dissentient.

Poplar (London, E.).—On the recommendation of the Works Committee, the Board of Works have decided to discharge the reference of the notice of the Capital and Counties Electricity Supply Company (Limited) of their intention to apply for a Provisional Order.

Runcorn.—At the last meeting of the District Council the electric light question was discussed. The Rev. Dr. Gastoldi moved a resolution in favour of the introduction of the electric light and of the appointment of a committee to consider the subject. He said that the town was an exceptionally suitable one for the introduction of the electric light, as he thought that they would be able to obtain sufficient power from the waterworks and from the refuse destructor works which they would be shortly compelled to erect. The motion was amended so as to include the consideration of other methods of illumination by the committee, and was passed in this form.

Shoreditch (London, E.).—Progress with the erection of the electricity generating station has been barred for some time, owing to certain demands on the part of the London County Council that the building line in Bowling Green-walk should be placed further back than originally agreed to. At the last meeting of the Vestry it was stated that this obstacle had been overcome, and that the amended plans had been sanctioned by the Council. The work will now be proceeded with as speedily as possible.

St. James's (London, S.W.).—At the last meeting of the Vestry the Works Committee presented a report on the question of lighting the principal streets of the parish by electricity. The Committee had before them schemes submitted by the St. James's and Pall Mall Electric Light Company and the London Electric Supply Corporation. As the Committee wished to obtain further particulars of the St. James's and Pall Mall Company's scheme, the general manager of the Company (Mr. F. J. Walker) subsequently submitted a modified plan showing the positions of the 69 arc lamps which the scheme provided for. If the Company undertook the laying of mains a sum of £5,000 would be required for that purpose, and, subject to a satisfactory arrangement as regards the period of the contract to enable the Company to make provision for this outlay, they would be willing to supply current, and to maintain in full running order each of the lamps requiring a current of 10 amperes, for the sum of £30 per annum. The Vestry would have to supply and erect the lamp-posts complete with lamps, and the Company would supply all mains, connections, switches, &c. The Committee recommended that experiments be made with incandescent gas burners in Regent-street before they proceed further in the matter. A discussion arose on the motion for the confirmation of the Committee's report, and Mr. Jenkins moved that it be an instruction to the Committee that an arc lamp be erected over one of the refuges in Regent-street while their lighting experiments were being made. They would then be able to compare the difference between the two methods of illumination. The instruction having been carried, the Committee's report was adopted.

Swansea.—In our last issue we mentioned that the Town Council had adopted the report of the Electric Lighting Committee, recommending the introduction of the electric light into Swansea and the adoption of a high-tension alternating-current system of electric supply. Notice of motion has been given by Councillor Viner Leeder for the next meeting of the Council that the principle of the electric light be adopted, but that the system to be employed shall be further considered.

Tottenham (Middlesex).—At the last meeting of the District Council a letter was read from the Town and Village Electric Light Company drawing attention to the advantages to be derived from the adoption of the Parfitt system of electric lighting. After some discussion the matter was referred to the General Purposes Committee for consideration and report.

Wakefield.—The Electric Lighting Committee reported at the meeting of the City Council on Tuesday last that they were making satisfactory progress with the electric lighting scheme, and that they were now awaiting the sanction of the Local Government Board to borrow the necessary money. Councillor Lee, in moving the adoption of the report, urged the importance of pushing on with the work, as some large customers were anxious to light their premises electrically, and unless current were available within a reasonable time they would probably put down their own generating plant.

Wells.—Dr. John Hopkinson has presented his report on the electric lighting question. The City Council intend to apply for a Provisional Electric Lighting Order.

Weybridge.—The District Council have now obtained counsel's opinion as to the validity of the contract recently entered into by them with the gas company. The opinion is to the effect that the contract could not be enforced. At the last meeting of the Council, Mr. Bilney severely criticised the action of the Council in so hastily entering into the contract. They had paid an exorbitant price for the gas—£2. 2s. a light. They had, therefore, lost £100 over the transaction. The Council should have accepted the Electric Light Company's offer to continue the lighting for another three months, and in the meantime they could have negotiated with them for better terms; but the Council had never negotiated with the Company at all. It was eventually decided to instruct the clerk to submit to the gas company the terms upon which the Council are prepared to enter into a fresh contract, and a special meeting of the Council to consider the matter will be held on the 16th inst.

Wigan.—At the last meeting of the Town Council the report of the Electric Lighting Committee was presented. The report recommended the adoption of an electric lighting scheme, which would involve an initial expenditure of about £16,000. After an amendment that the advice of an electrical expert be obtained before proceeding further with the matter had been rejected, the Committee's report was adopted.

Worcester.—The City Council intend to apply to the Local Government Board for sanction to borrow £1,300 for wiring the Guildhall and the Public Hall for the electric light.

Workhouse Lighting.—At a meeting of the Lighting Committee of the Newcastle Guardians last week it was decided to engage the services of Mr. D. Selby Bigge and Mr. John Thompson to report on the lighting of the workhouse by electricity and the probable cost thereof.

Works Lighting.—Messrs. A. J. King and Co., proprietors of the Ingersley Vale Bleach Works, Bollington, near Macclesfield, intend to light the whole of their premises electrically. The work has been placed with Messrs. Mather and Platt, of Salford, who have also received an order for the supply of an electric motor for driving machinery in the firm's new shed.——The whole of the Conisborough Glass Works are to be lighted electrically. The contract for supplying the necessary generating plant, wiring and fitting has been placed with Mr. J. A. Edmondson, of Leeds.

COMPANIES' MEETINGS AND REPORTS.

Willans and Robinson (Limited).

The ordinary general meeting of the shareholders in this Company was held at the City Terminus Hotel, Cannon-street, on Tuesday, under the presidency of Mr. Mark Robinson, M.Inst.C.E.

The Secretary (Mr. C. S. Essex) read the notice calling the meeting, and the report of the Directors was taken as read.

The Chairman then said: In rising to move the adoption of the report and accounts I can again congratulate you, on behalf of the Directors, upon a prosperous and encouraging half-year. We have had, as the report points out, something of a windfall, but even without this the results would have been better than last half-year. It is true that we do not show a profit exceeding that of last half-year by quite the amount of the windfall, but that is only because we have already applied a portion of our windfall to increasing an already liberal rate of depreciation before the calculation of profit is arrived at. To write down one's assets faster than ordinary prudent book-keeping requires, is but another way of carrying to reserve, so that the handsome reserve fund of £5,146 to which we now attain as the result of our first eighteen months' work, is by no means the total measure of our savings. That we have done better than last half-year is important for two reasons. First, we have had to bear the burden of much idle capital intended for the Rugby extension, which obliges us to earn more dividend without helping us to earn it. So far we have met the obligation—and a little more—even without our windfall. Do not forget, however, that for the next half-year or two, until Rugby is fairly at work, this is an evil which must tend to increase. Secondly, the first half of the year is usually our worst half, a fact which should give us anticipatory comfort for the half-year which is now passing. As regards dividend, we hope our action in continuing it at 7 per cent. will meet your approval. It would be easy to divide more; we could pay 12 per cent. if we were so ill-advised, but it would not be prudent, and after all 7 per cent. is more than a good many things yield. If we can keep up that interest in a time of transition, while continuing to build up a large reserve, we shall feel that we have fulfilled our promises in the present, and have given you good hope of surpassing them in the future. Increasing orders must be, of course, a

Digitized by Google

ground for congratulation. Yet it is difficult to express how this increase adds to the labours and the anxieties of the management, and how seriously it upsets the smooth working of the business. We cannot greatly increase our output until Rugby is ready, and therefore to encourage the same rate of increase of orders through the present half-year would be unwise, since the figures of the second half of 1894 were swelled by one exceptional order, the execution of which is responsible for much of the congestion in the half-year now under review. You will naturally wish to know something of the steps we are taking to remedy this state of things, and to bring us fairly in line with the business which waits for us. As regards time, we shall not, I am sorry to say, achieve our original aim of having the new works in operation by Christmas. The new foundry may give us help at an earlier date, but the machine shop cannot aid us much until the spring is well advanced. With regard to the scope and magnitude of the new works, the original intention was to start in some suitable place with a considerable foundry, and with a small machine shop, the latter being wholly an adjunct to Thames Ditton, where only repetition work—*i.e.*, standard parts of engines made to gauge, and requiring little other than a foreman's supervision—should be carried out; it should thus act only as a feeder to Thames Ditton, where the parts made elsewhere would be examined and passed, and where the engines would still be put together and afterwards tested. We contemplated from the first that this arrangement could be only a temporary one, and that eventually the northern works must be the larger of the two, and must become the headquarters of the business. However, by the time the Rugby site was decided upon it had become evident that before the contracts could be placed this subject might be found ripe for decision, and it has in fact become so. It was simply a question of the rate of the increase of our business, and that rate has so accelerated of late that our decision could not be in doubt. The least extension which could reasonably be made involved the practical doubling of the present machine-shop floor space—that is, we had to build at Rugby a machine shop as large as the one at Ditton. Since we contemplate larger and heavier engines than can be properly made at Ditton, the new machine shop must be fitted with heavier tools and heavier travelling cranes than the present one; it must, in fact, be a better and more important shop. Obviously the engines should be erected, and of course tested where the heaviest work is done. At Thames Ditton we are terribly cramped in the erecting shop, and the testing department is perhaps, through want of room, the weakest spot of all. The time, then, has therefore come to move these departments to Rugby, and with them such subsidiary departments as the pattern shop and the stores, as well as the staff and the head offices, must be moved. In other words, Rugby must be the headquarters from the first, and Thames Ditton the adjunct. Given a sufficiency of orders, which does not seem doubtful, there is evident advantage in making the change at once, rather than piecemeal, and so we trust that before our next October meeting we shall date our letters from Rugby, and shall be able to feel that we are doing our constructive work under far more favourable conditions than at present, while still enjoying the advantages of concentration. As regards the works at Thames Ditton, these are well adapted for just that class of standard light work which it was at first intended to begin with in the North. The heavier tools at Ditton will be removed to Rugby, but the lighter standard parts, which are made to invariable gauges and templates, can continue to be made at Ditton with but small intervention on the part of the superior staff. In order to save time, only the principal and most urgent buildings have, so far, been put in hand at Rugby; but plans for the remainder are in preparation, and, with the exception of the offices, they should be ready at about the same time as the other buildings already under construction. It is thus premature to speak definitely of the cost of the buildings, or of the new tools required; but the Directors are satisfied, from the contracts now placed, that very substantial and efficient shops will be obtained at a cost which will compare favourably with that of the shops at Thames Ditton. It may be of interest to the shareholders to know that the machine shop now building (including under the same roof a large erecting shop and ample stores) measures about 300ft. by 100ft., or 30,000 sq. ft. of floor space, against about 20,000 sq. ft. in the Thames Ditton machine and erecting shops. At Ditton the testing department occupies a small corner of the machine shop; at Rugby, the testing department is a separate building. The Rugby foundry will be of considerable size, covering, with its dependent buildings, some 20,000 sq. ft., and it will have available floor space some five or six times greater than that of the foundry at Ditton. The latter, it should be remembered, supplies only a small part of the castings we use; at Rugby we hope to make all ourselves. Some of the new tools for Rugby have been purchased already, and are doing us excellent service in a temporary shop not far from the works at Ditton. We hope soon to add to the number of tools so employed. The debenture debt has been paid off, and it may be added that we have given notice to pay off the mortgage on the Thames Ditton freehold, so as to set our hands completely free against the time when an issue of debentures may be found necessary. The extension of our foreign licence business is of good augury in every way. Continental work is not easily carried on from here, as in most European countries there is prejudice against engines not of home manufacture, while the cost of sending over to erect, as well as to explain and instruct, makes such business relatively unprofitable. It is better to receive a reasonable royalty upon engines made by licensees, and to keep one's capital and appliances for the more remunerative home and colonial business. It is as important as it is difficult to secure licensees both able and eager to do thorough justice to the engine, but we believe that, as the outcome of long and patient negotiations, the Willans engine will now be made abroad by firms whose capacity and position is thoroughly satisfactory, so that we may look forward with some confidence to the receipt of a substantial income from royalties. I regret to say that the question of the Stock Exchange quotation is still unsettled, though I believe there is no doubt about its being granted. We were last half-year under the impression that if we issued the remainder of the capital whose issue has already been authorised, we should be able to comply with the Stock Exchange requirements as to the relative proportions of capital offered and not offered to the public. The issue was made without difficulty, and we supposed that the quotation would follow. But it seems that it cannot be given until the shares are not only issued, but paid up in full, and not only paid up in full, but paid up so long since that the next dividend to accrue shall be a *full* dividend upon every share. Unfortunately, since the money was obviously not wanted at once, we arranged with some of the shareholders to make their payments over a long period, in some few cases extending beyond the current half-year. These we shall endeavour to get in before the half-year closes, and then, though the dividend upon these shares payable next spring will be for only part of a half-year, as soon as that dividend is paid a full dividend will be accruing for next time. According to this we must renew our application in just six months time. He concluded by moving the adoption of the report and accounts.

Mr. ERSKINE (a shareholder) seconded the motion.

A short discussion followed, in which Messrs. ROSE, BRYAN DONKIN, ANDERSON, and G. B. CLIFTON took part.

The CHAIRMAN, in reply, stated that no arrangement had been made by the Company with their licensees as to the price at which engines made by the latter might be sold. They had granted licences in certain foreign countries because they believed that their engines could be made cheaper there than by the Company here, the Company being shut out from those countries by high tariffs. The foreign manufacturers, however, would pay this Company a royalty. They could compete with the Company in far-off corners of the world, as, for instance, Japan or South America, but he could see no harm in such competition. If foreign makers sold the engines in those places they would not sell them instead of the Company doing so, but in addition to the Company's sales, and pay a royalty to them. They could not compete in England, or in countries in which the Company were really interested. With regard to the increase of £1,379 in the item of patents in the half-year, the bulk of this addition was in the gas engine patent account. They had for the time concluded their experiments with the gas engine under test for a couple of years. He thought that all it would be wise for him to say at the present time on this matter was that they believed they had acquired very valuable information upon the subject for the amount they had expended on the tests, and that as soon as they had time and space at Rugby to think of the matter, they would be able to go on with gas and oil engines, and with greater advantage in consequence of the experiments in question. The particular engine which they had had in view they did not like, and they had come to the conclusion that it would not be wise to pay the high price asked for it, and they believed that they would go on just as well without having to make the payment. The sum paid by them for the patent for the Niclausse boiler was included last half-year, or the half-year before that, in their patents account. He might say that this boiler promised very well indeed, but it was useless for them to ask for orders for it, because they had not at present the means to execute them. They could have taken plenty of orders for the boiler if they had been in a position to execute them. The principal boiler which would be used at the Company's new works would be the Niclausse. He had been glad to hear the encouraging remarks of Mr. Bryan Donkin regarding the reserve fund, which he hoped they would be able to build up very quickly. The sum they received for their grant of a sub-licence for the Niclausse boiler was included last time under the foreign licences account. The two engines which were under construction for Heilmann locomotives were not completed; in fact, the locomotives themselves were not ready for the engines. The dividend recommended would be paid on the following day. They only got 1 per cent. interest on their money at the bank. They had invested a sum of nearly £10,000 for the debenture sinking fund, and when the debentures were paid off they still retained those investments, so that a part of their surplus cash was now invested in addition to the reserve fund.

The motion was then unanimously adopted.

The CHAIRMAN afterwards proposed a resolution declaring a dividend for the half-year ended June 28th last at the rate of 6 per cent. per annum on the capital paid up on the Preference shares, and at the rate of 7 per cent. per annum on the capital paid up on the Ordinary shares.

Mr. ANDERSON seconded the resolution, which was unanimously adopted.

On the motion of Mr. ANDERSON, seconded by Mr. BRYAN DONKIN, a cordial vote of thanks was passed to the Chairman and Directors for the able way in which they had conducted the affairs of the Company.

The CHAIRMAN, in acknowledging the vote, remarked that the Directors did their best to obtain the shareholders' approval. He hoped that they would be able to show in the future that they had acted wisely in what they had done so far.

The proceedings then terminated.

Westinghouse Electric Company (Limited).

The following is the report of the Directors of this Company for the year ended September 30, 1894, to be presented at the fifth annual general meeting of shareholders, to be held at the offices, 4, Victoria-mansions, 32, Victoria-street, S.W., on Tuesday next, 15th instant, at four o'clock:—

The agreement between the English and American Companies, referred to in the last report and approved by the shareholders at the last general meeting, has been carried out. After providing for all expenses of management, Directors' fees, depreciation, patent taxes, and other expenses connected with the maintenance of the various English and foreign patents owned by the Company, there is a net profit for the year amounting to £7,725. 1s. 11d., which, added to the sum brought forward from the

Digitized by Google

previous accounts, makes a total of £20,739. 18s. 7d. to the credit of profit and loss, which the Directors propose to carry forward.

Owing to the continued increase in the sales of the Shallenberger meter, the Directors have found it necessary to provide more extensive laboratory accommodation for the purpose of ensuring careful tests and adjustments of the meters being made before despatching them to purchasers. The Directors have secured this accommodation at their Chelsea warehouse, and they have now a laboratory complete with the very best instruments and apparatus necessary for testing purposes. The sales of meters during 1894 have been satisfactory, and orders for transformers and other apparatus were also in excess of those of previous years.

Mr. Oscar H. Baldwin, who was previously associated with the English Company, has, on the recommendation of Mr. Westinghouse, been appointed manager of the Company with a seat on the Board. The Directors have purchased a controlling interest in the European patents, covering a new system of electric traction, in which the conductors are placed underground, and which they believe will prove to be a very valuable asset. They have also agreed with the American Company on a new and more favourable basis of prices for all apparatus manufactured by that Company, which they think should prove advantageous and lead to increased business.

The retiring Director is Mr. Albert Kapteyn, who, being eligible, offers himself for re-election, as do also the auditors, Messrs. Price, Waterhouse and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c., &c.*

HEADLAND'S PATENT ELECTRIC STORAGE BATTERY COMPANY (LTD.). This Company was registered on October 5th with a capital of £15,000, in £1 shares, to purchase or otherwise acquire and take over as a going concern the business of electricians at present carried on under the style of "H. and E. Headland," at Leyton, Essex, to enter into an agreement for the acquisition of same, and to carry on the business of electricians, electrical apparatus manufacturers, &c. The subscribers, with one share each, are: E. E. Cronk, J. H. Oxley, F. Cronk, P. J. McManus, T. Byron, H. W. Headland, electrician, and A. F. White. Mr. H. W. Headland is to act as works manager of the Company.

CROMPTON AND CO. (LIMITED).—The annual return to August 23rd has been filed. The capital is £280,000, in 30,000 Preference and 26,000 Ordinary shares of £5 each. 28,180 of the former and 5,928 of the latter have been taken up, and 4,000 Ordinary have been issued as fully paid. The full amount has been called on the Preference, and one pound per share on 1,928 Ordinary shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 31d. per oz. (Oct. 10th). Consols (2¾ per cent.) 107⅜—107⅝ for money, 107 7/16—107 9/16 for account (Oct. 10th); 2½ per cent. 105¾—106¼. Stock Exchange Settling Days: Consols, Nov. 6th; Stocks and Shares Continuation Day, Oct. 14th; Ticket Day, Oct. 15th; Pay Day, Oct. 16th; Mining Shares Carry-over Day, Oct. 12th.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Board of Directors have resolved, after placing £6,000 to the credit of the Renewal Fund, to declare an interim dividend for the quarter ended September 30th of 10s. per cent. on the Ordinary stock and 20s. per cent. on the Preferred stock, less income tax. The dividend is payable on November 1st.

BERLINER ELEKTRICITATS-WERKE.—The report for the year 1894-95, just issued by this Company, shows a profit of £79,822, as compared with £64,652 in the preceding year. It is proposed to declare a dividend of 12½ per cent., as against 10½ per cent. for the year 1893-94.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended October 6th were £887, against £892 in the corresponding week of 1894, a decrease of £5. The total receipts for the half-year amount to £11,858, against £12,011 for the corresponding period of 1894, or a decrease of £153.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of September amounted to £62,586, against £57,368 in the corresponding period last year, an increase of £5,218.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of September amounted to £52,678, and to £40,178 in the corresponding period of 1894, or an increase of £12,500.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of September amounted to £28,400. The traffics from January 1st to September 30th amounted to £231,200, and for the corresponding months in 1894 and 1893, £207,400 and £203,600 respectively

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 6th inst. amounted to £1,088. The amount for the corresponding week last year was £908; increase, £180.

LUGANO ELECTRIC TRAMWAY COMPANY.—A Company has recently been formed at Lugano, with a capital of £8,000, to be known as the Tramvie Elettriche à Lugano, to construct and operate an electric tramway from the Paradiso in Lugano to Cassarate, with a branch to Moule-Nunif.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—During the week this Company issued a prospectus inviting subscriptions for 100,000 Five per Cent. Accumulative Preference Shares of £1 each, payable 5s. on application, 5s. on allotment, and 10s. on 31st inst. The Ordinary share capital of the Company is £300,000, £260,000 whereof has been issued. The shares now offered to the public are redeemable at any time after January 1, 1905, at 105 per cent. The Salt Lake and Ogden Gas and Electric Light Company of Utah (U.S.A.) was formed in 1893, with a capital of $1,500,000, for the purpose of acquiring the franchises extending to the year 1919, and consolidating the several undertakings previously carried on in Salt Lake City and Ogden for the supply of electric light, gas, and power. That Company created an issue of $1,500,000 (£300,000) Six per Cent. First Mortgage Gold Bonds, and $1,250,000 (£250,000) of these have been issued. The whole of the shares and the entire management of the Utah Company are under the control of the English Company, which was formed in 1893. The proceeds of the present issue will be applied to the purchase of an equal amount of bonds of the Utah Company. The offices of the Company are 251, Winchester House, Old Broad-street, E.C., and the Secretary is Mr. J. N. Kelman. The lists opened on Wednesday last, and close to-day (Friday) at 4 p.m. for both town and country.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Tuesday next, October 15th, a settling day in 9,104 fully-paid £10 shares and 207,649 £10 shares (£2-paid) of the Central London Railway Company (Limited), and have also ordered the same, together with the further issue of 3,498 Seven per Cent. Cumulative Preference shares (Nos. 12,846 to 16,343) of the Electric Construction Company (Limited), and the further issue of 3,163 Ordinary shares (Nos. 1 to 601, 1,092 to 1,181 and 7,529 to 10,000) of W. T. Henley's Telegraph Works Company (Limited), to be quoted in the Official List.

SUBMARINE CABLES TRUST.—Notice is given that on and after the 15th inst. the sum of £1. 15s. on account of the coupon due 15th inst. will be paid by Messrs. Glyn, Mills and Co., 67, Lombard-street, London, E.C., between the hours of 10 a.m. and 2 p.m. Coupons should be left four clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended October 4th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,071.

WESTERN UNION TELEGRAPH COMPANY.—This Company have issued their report for the quarter ended September 30, 1895:—The following statement, dated September 11th, exhibits the condition of the Company at the close of the quarter ended June 30, 1895:—

Surplus April 1, 1895, as per last quarterly report......		$7,260,082. 75
Net revenues, quarter ended June 30, 1895..............		1,583,048. 80
		$8,843,131. 55
From which deducting for—		
Dividend of 1¼ per cent. paid July 15	$1,191,941. 25	
Interest on bonded debt	223,713. 95	
Sinking funds........................	20,000. 00	
	$1,435,655. 20	
Less—		
Portion of Sinking Fund for the bonds of 1900 (which were set aside previously) returned to the Company by the Sinking Fund Trustees, because of the drawn bonds not being presented for redemption...	$40,000. 00	
		1,395,655. 20
Left a surplus July 1st, as above		$7,447,476. 35
The net revenues of the quarter ended September 30th, based upon nearly completed returns for July, partial returns for August, and estimating the business for September, would be about..............		1,850,000. 00
		$9,297,476. 35
From which appropriating for—		
Interest on bonds	$223,500. 00	
Sinking funds	20,000. 00	
		243,500. 00
		$9,053,976. 35
It requires for a dividend of 1¼ per cent. on capital stock issued, about		1,191,945. 00
Deducting which leaves a surplus, after paying dividend, of		$7,862,031. 35

In view of the preceding statements, the Committee recommend that a dividend of 1¼ per cent. on the capital stock of this Company be declared payable on and after the 15th instant. The stock books of the Company are closed from September 20th to 15th instant.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended September 30th were £1,703, as compared with £2,679 in the corresponding period of 1894. The June receipts, estimated at £3,939, realised £3,958

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 909. [No. 25. Vol. XXXV.] FRIDAY, OCTOBER 18, 1895. PRICE SIXPENCE.

NOTES.

When municipalities acquire tramways, they cannot do better than work them to the best advantage. One means to this end is careful administration; but no amount of good management will make amends for a radically defective system of haulage. At the same time municipalities cannot be too cautious in adventuring the ratepayers' money in untried schemes. It is possible, however, to handle a matter of this kind in an over-timorous manner. Between enthusiastically adopting every untried novelty emanating from fertile engineering brains, and never adopting anything new for fear that it may be out of date before it is paid for, there is a golden mean. This golden mean, it seems to us, has been admirably attained by the Leeds City Council, which recently took over a more or less worn-out tramway network. The good people of Leeds immediately clamoured for lower fares and better service, and the merits of half-a-dozen different systems of traction were incontinently thrust upon the attention of the city fathers; not only so, but, as Alderman Ward somewhat bluntly remarked, "so many experts offered their services that the Committee found them a nuisance." Under these circumstances the City Council wisely appointed a special committee to deal with the entire question, and it is the exhaustive report compiled by this Committee and Mr. Hewson, the borough engineer, that the Leeds City Council adopted on Tuesday last by 40 votes to 11. Electric traction has triumphed over all its competitors. Steam haulage, it was felt, "ought not to be tolerated" any longer. Gas and oil cars, the Committee were unanimously of opinion, "would not do for Leeds." The choice lay between cable and electric cars, a combination of the two being dismissed as impracticable. The borough engineer's estimate of the initial cost of the cable system and the electric system was £428,922 and £378,499 respectively, the respective annual working costs being estimated at £111,819 and £90,072. The eloquence of this estimate, added to American *facts*, carried the day, and the principle of electric traction was adopted for Leeds, though before the City commits itself definitely to the large expenditure indicated, the overhead trolley and the underground conduit system are to be pitted against each other. We can only hope that those who have sown the seed will reap their fair share of the harvest now evidently ready for the sickle. The success of the Roundhay Park line was the last straw that broke the back of the opposition at Leeds.

In an article, copiously illustrated by diagrams, which will be found in our columns this week, Mr. Clarence P. Feldmann discusses "The Influence of the Shape of the E.M.F. Curve upon the Iron Losses of Alternating-Current Transformers," and adds one further contribution to the controversial literature of the "true sine curve." American manufacturers, we fear, will believe that Mr. Feldmann gives himself and his plea away at the outset, where he talks of "the legendary ground of the pure sine curve." To their manner of thinking the true simple harmonic curve of electromotive force is anything but legendary. However, the interesting series of curves which Mr. Feldmann has carefully compiled teaches us that, whether legendary or not, the pure sine curve need not worry the practical engineer. Rather than strive to impart its simplified purity to his alternate-current machinery, which a benevolent Providence has wisely made it extremely difficult for him to do, the designer or the constructor of such plant should hold this form of curve in taboo. We do not now desire to resuscitate the controversial side of an inquiry, one of the useful effects of which has been to stimulate widespread research into the comparative values for various purposes of waves of different type. The controversial side of the matter has, we believe, long since been set at rest by the dead-weight of an immense mass of experimental and practical evidence. Mr. Feldmann does but add one more to the large number of facts which tell in favour of the flatter type of curve of electromotive force.

While perusing an article on "The Kinetic Theory of Gases, regarded as Illustrating Nature," in the current number of the *Philosophical Magazine*, we noticed that the introductory part furnished a most lucid and interesting summary of the metaphysical connection between phenomena and the logic of research. We have therefore taken the liberty to clip off the introduction to Dr. Johnstone Stoney's article on the kinetic theory, and to publish this under the new title, "Phenomena and Research"; for this delightful exposition of the underlying connection between what we see, what is, and what we may deduce, is worthy of the attention of all who seek to wrest her secrets from Nature's hidden recesses, whether in connection with electrical or any other phenomena. Particularly useful i

Digitized by Google

that part of his introduction, in which Dr. Stoney shows the true logical importance of mechanical illustrations of phenomena. In such cases it is not Nature herself that is under examination and study, but a simplified and partial representation of Nature. The value of all such illustrations depends upon the success with which the observer takes proper note of the modifying influence which the characteristics that are absent from the illustration exert in the actual real phenomena. It is to the neglect of this precaution that the innumerable short-lived and erroneous hypotheses of this, that and the other branch of physical science are chiefly due.

In our "American Notes" this week will be found a detailed account of the "latest" phase of the Niagara-Buffalo franchise negotiations. At first it would seem that the Buffalo municipal authorities, thinking they had the whip hand of the Niagara Falls Power Company, devoted themselves to the pleasant task of exacting the maximum possible profit out of that concern. Now, however, our New York correspondent tells us that "the attitude of the Niagara Company is considered by many people to confirm their belief that the talk of transmitting the power of Niagara to a distance was a mere blind, the Niagara enterprise being primarily a land-jobbing scheme, which expects to derive profit, not from the electrical plant in itself, but in leases and rentals from the vast landed property which it possesses in the immediate vicinity of the power house, and now being developed as a manufacturing centre." If this be so, the social millenium would seem to be nearly as far off as ever, and Messrs. Houston and Kennelly's calculations as to the exact cost at x miles from the Falls of an electrically transmitted Horse-Power Hour, x being any number from 0 up to 500, have been more or less wasted. The true inwardness of things American is always to be found very deep down, and we are not, therefore, prepared to accept the latest explanation of the why and wherefore of the Niagara power plant as the last.

The idea of building up a complete collection of catalogues which, as Messrs. Johnson and Phillips point out in our "Correspondence" columns this week, has found favour in the eyes of the officials of the United States Patent Office, is, commercially, technically, and historically speaking, an altogether admirable one, the only drawback that occurs to us being the possibility that the world may not prove big enough to contain a complete file of this unrecorded "literature." This, however, is a remote contingency which may safely be left to posterity to deal with. As the circular-letter of the United States Patent Office points out, a file of this kind will prove invaluable in patent cases in determining the exact meaning assigned in any particular industry at any particular time to recondite technical terms. But the file is to be kept for "other purposes." What may these be? Perchance they may have something to do with imitation, plagiarism, and the posting-up of the acute American in the latest foreign manufacturing developments. Now we have it on the authority of no less a personage than John Stuart Mill—and on that of common sense—that no one can reasonably be expected to be indifferent to his own immediate interests unless other people are made to follow his example. That being so, the plan of the United States Patent Office may very possibly not be supported by foreigners unless there is reciprocity, unless American manufacturers show *their* readiness to aid the good work, and unless the English, French, and German Patent Offices also keep a file of catalogues.

The cool courage of those unfortunate individuals who are afflicted with the inventive mania is a somewhat well-worn theme; but, notwithstanding, we must be allowed to record an instance of it which recently came to our notice. For years men trained in the glow-lamp industry—one of the few still surviving in which secret processes are the order of the day—have been at work, endeavouring to improve the efficiency of glow-lamp filaments by using refractory oxides, and at the present moment a company is, we believe, about to be brought out in this country to exploit the Langhens patents. Nevertheless, an individual has been found brave enough to devote his time and his money to laborious experimenting in this direction, and in order that he may not be biassed by an undue knowledge of what others have done or are doing, he has taken the precaution of ignoring all patent and technical literature on the subject, feeling, of course, quite sure that *his* idea is quite new. Valour of this kind surely merits the Victoria Cross.

A correspondent says that "already we have a circle of polytechnics girdling London." The effect of this belt of learning is, we are told, "the rapid democratisation of the present age." We also note that at some of the points in this largely invisible girdle classes are specially held for "formula-using students"—a most objectionable type of seeker after knowledge. We hope the object of these special classes is the utter extermination of the species.

Cable Interruptions and Repairs :—

	Date of Interruption.
Cadiz-Teneriffe	Sept. 25, 1895.
Maranharn-Para	Oct. 10, 1895.

Clerk Maxwell Scholarship.—The Clerk Maxwell Scholarship is vacant by the resignation of Mr. W. C. D. Whetham, M.A., of Trinity College. Candidates must send their applications to Prof. Thomson, Cavendish Laboratory, on or before November 1st.

International Telephonic Communication.—Belgium and Germany are now in direct telephonic communication with each other. Antwerp and Cologne are the extreme points between which conversations can be carried on, and the price for three minutes' use of the line varies from 1fr. 25c. to 2fr., according to the distance. The new Copenhagen-Hamburg-Berlin telephone trunk line came into operation on the 9th inst.

Finsbury Technical College.—We see by the programme recently issued in connection with the City and Guilds Technical College, Finsbury, that there are at present in attendance 200 day students, ranging from 15 to 19 years of age, and about 1,000 evening students, whose ages vary between 14 and 40 years. Besides the usual courses of lectures and laboratory instruction in pure and applied science, the forthcoming winter session will include a number of short courses of lectures on special subjects, notices of which will appear in our columns from time to time.

Digitized by Google

Holophane Globes.—Notice is given that Spiridion Psaroudaki, of 96, Boulevard de Grevelle, and André Blondel, of 2, Boulevard Raspail, both of Paris, have applied for leave to amend the specification of the Letters Patent No. 19,185, of 1893, for improvements in the diffusion and distribution of light. Particulars of the proposed amendment were set forth in the Illustrated Official Journal (Patents) issued on October 2, 1895. Any person or persons may give notice of opposition to the amendment (on Form G) at the Patent Office, 25, Southampton-buildings, London, W.C., within one calendar month from the date of the said journal.

The United States-Haiti Cable.—The *New York Herald* of September 24th announces simultaneously the formation of the United States-Haiti Cable Company and the laying of the New York shore-end of the projected cable by the s.s. "Mackay Bennett." The shore-end at New York is 10 miles long, and terminates close to the Commercial Cable station at Coney island. In Haiti the landing place will be Puerto Plata. There the Company will connect direct with the French system of cables, and will collect for them at New York traffic for Venezuela, Dutch and French Guiana, Brazil, and the West Indies generally. The Directors of the United States-Haiti Cable Company are John W. Mackay, George W. Ward, J. W. Mackay, jun., A. B. Chandler and Albert Beck.

Search Lights and Strikers.—We have received the following from Messrs. Baxendale and Co., of Manchester :—

"We would like to bring before your notice rather a novel use of the search light in connection with the strike and riots at Messrs. Gartside's works, near Stalybridge. We received instructions from this firm to fix one of our "ship canal" search-light plants at their works, with the idea of preventing the strikers from maliciously setting fire to the temporary sheds erected for the protection of the men at present employed. A few hours after the receipt of their order we had this plant running on the top of the works, and it is now being used nightly, in conjunction with the police force established at the works, to scour the surrounding country, and for illuminating the various parts where pickets are placed. We are informed that the light used for this purpose is a perfect success, and enables them to dispense with a considerable number of temporary police. We think that perhaps this description may be of interest to some of your readers, as it is, so far as we are aware, the first time a projector has been used for this purpose."

Obituary.—It is with deep regret that we have to announce the sad death on Sunday last of Mr. Franklin Leonard Pope, one of the best known and most popular men in the American electrical world. According to a cablegram received from New York as we go to press the circumstances of Mr. Pope's death were as follows :—On Sunday evening, as darkness approached, it was found that the glow lamps in Mr. Pope's house would not light up properly. Mr. Pope thereupon went down to the cellar to examine the transformer. Not long after, members of the family heard a thud and an explosion. On going down to see what was wrong Mr. Pope was found lifeless, his body lying beside the transformer. The exact manner in which the fatality occurred has not yet been ascertained—Mr. Pope began life as a telegraphist, and after doing duty with several pioneer companies, joined the service of the Western Union Company, which he left about 1880, to practise as a consulting electrical engineer and patent expert. Latterly he became connected with the Westinghouse Company, acting as their expert in connection with their Tesla patent litigation. Mr. Pope has been President of the American Institute of Electrical Engineers, and was the original proprietor and editor of our esteemed contemporary, the *Electrical Engineer* of New York. He was a frequent and valued contributor to the technical journals and the author of several works, one of which was a small and capital book on the evolution of the incandescent lamp. Mr. Pope was a frequent visitor to this country, and endeared himself to a large circle of friends by his kindly manner. He was about 60 years of age.

Inverted Arcs in a Worsted Mill.—An article in the *Electrical Engineer* of New York describes the use of inverted arc lamps in a worsted mill in America, and gives some data for a comparison between the cost of this and of other methods of illumination. The tests were made during the month of January in the present year, and the first room to be subjected to experiment was the braiding room, 136ft. long, 66ft. wide and 12ft. high. The machinery consists of 420 machines, arranged in 14 parallel rows. Formerly the room had been lit by 84 gas jets; but eight inverted arcs replace these, the arc lamps being placed in two parallel rows at 17ft. distance from the side walls. Nine-ampere lamps were used. When lit by gas (6s. per thousand) the cost of a 2½-hours evening run was 9·32 shillings; but when the arcs were used the cost (current at 7½d. per kilowatt hour) was reduced to 5·92 shillings, showing a saving of 47 per cent. in favour of the arc lighting. Next an experiment was made in the worsted spinning room, which had the same dimensions as the other room, and which was furnished with 24 spinning frames, 12 twisters, and three spooling machines. Here 10 inverted arcs replaced and gave a better light than 82 gas jets, the actual saving in the cost of a 2½-hours evening run being 33·3 per cent. in favour of the arc lamps.

Power Required for Electric Traction.—In the early days of mechanical traction for street cars, says *Engineering*, "the estimates of the power requisite were frequently ludicrously low. As a couple of not very powerful horses could draw a heavy tramcar without much difficulty, it was argued that two or three horse-power applied mechanically should do the same thing, it being notorious that Watt's estimate of the number of foot-pounds in a horse-power was excessive. There should, therefore, have been a good margin in favour of the mechanical system. Experience proved the reverse to be the case, the reason being that though no ordinary horse can do 33,000 foot-pounds of work per minute continuously, he can for a small fraction of time do very much more, which is not usually the case with a mechanical motor. Hence the horse-power required for mechanical traction can only be determined by experiment and experience. In an article in the *Sibley Journal of Engineering*, Mr. James Lyman gives the results of a number of tests made in different American cities of the power required for electric traction. At Rochester, where the first of Mr. Lyman's records were obtained, there are about 20 miles of track which was in good condition at the time of the test. The number of cars on the road was 40, each weighing about eight tons and provided with a 15 H.P. geared motor. In general the road was level, but in the heart of the town there were some gradients of from 3 to 4·7 per cent. Moving on the level the necessary tractive power averaged 38lb. per ton of car, and for the whole run over the four principal routes at 6·5 miles per hour, the average horse-power was 1·4 per car, and the maximum 6 H.P., this latter being used only momentarily. At Buffalo the same average power was required, but the maximum was 6·6 H.P. In a large western city a car with the axles coupled direct to the motor, without the intervention of gearing, took 0·92 H.P. per car on the average, with a maximum of 4·7 H.P. In wet weather the tractive power required is reduced, the rain acting as a lubricant. Wetting of the rails round curves is particularly effective, the requisite tractive power being thereby reduced by one-third."

The Electric Light and Power Equipment of the Birmingham Technical School.—The electric lighting of this School was carried out by Messrs. B. Verity and Sons according to the plans and specifications of Messrs. Henry Lea and Thornbery. The generating plant consists of three 53 B.H.P. Tangye gas engines running at 160 revolutions. The three compound-wound Parker dynamos run at 900 revolutions, and are belt-driven. The engine room also contains a small Tangye gas engine, used for compressing a mixture of gas and air for starting the main engines. Instead of the usual cylindrical vessels a large cast-iron tank, 24ft. by 16ft. by 3ft. deep, holding 6,000 gallons of water, is placed above the battery room, of which it forms the roof. The dynamos, by aid of a "booster," are able to charge a 58-cell battery of E.P.S. storage cells. The Principal of the School (Dr. W. E. Sumpner) has, in conference with the engineers, given special consideration to the character of the lighting of the rooms throughout the building, so as to adapt it as much as possible to the various wants of the classes. In some rooms the usual 16 c.p. glow lamps are used, in others a smaller number of 50 c.p. glow lamps are found to be more suitable, in others Crompton arc lamps are used of the ordinary pattern, while in others again inverted arc lamps are employed. In the mechanical drawing office particularly this method of lighting is much appreciated, and in many of the workshops, where the shadows cast by ordinary

Digitized by Google

lights are objectionable, the inverted arc system has proved a great success. Electricity is freely used in the school for motive-power purposes. Thus there are 15 motors in the building, of a total of 46 H.P., varying from one to 7 H.P. each. The manufacture and fixing of the machinery and apparatus and the wiring of the building have proceeded very expeditiously and smoothly, no hitches of any kind having occurred. The first instructions were given to the contractors on May 23rd last, and the light was used for school purposes on September 16th, and has since then been nightly in use without interruption. There are in all about 806 glow lamps, 80 arc lamps, 13 miles of insulated copper conductors, and 30,000ft. of wood casing.

Newport.—The Newport municipal electric supply station was formally opened on Monday last, though current has been supplied for some time past from a temporary plant. The system employed is that of alternate-current transformer sub-stations. The transformers are placed in boxes in various parts of the town, and at a distance of about 200 yards from each other. The generating plant at present consists of four 75-kilowatt alternators of the Hall type by Messrs. Fowler and Co., cotton-rope coupled to four horizontal compound condensing engines of 150 I.H.P., manufactured by the Uskside Engineering Company of Newport. The steam plant comprises four Lancashire boilers fitted with Proctor's mechanical stokers. Meldrum's system of forced draught is also fitted to the boilers, being arranged for easy disconnection when the boilers are required to work with natural draught. The engines are run at a speed of 110 revolutions, and are fitted with Hartnell's vertical high-speed governors. Heavy flywheels of eight tons weight and 12ft. diameter are provided. They are grooved for eight ropes of 1¼in. diameter. The alternators run at a speed of 525 revolutions, and have a periodicity of 87 and an E.M.F. of 2,000 volts. The switch board is so arranged that all the alternators can be run in parallel. An emergency shunt is also fitted, so that any circuit can be run direct from any dynamo without the intervention of the omnibus bars. In a separate building a day load plant is erected. It consists of a semi-portable under-type engine and boiler for 50 I.H.P., driving a Hall alternator. The switch-board of this plant is connected with the main switch-board, and so arranged that the dynamo can be controlled at either board. The distribution is effected by a network of armoured cables of the Siemens type, laid direct in the ground. The high-pressure cables are of the vulcanised india-rubber class, and are drawn into cast-iron culverts and boxes laid chiefly under the pavement. The transformers are of the Lowrie-Hall type. There is also some street lighting, which is carried out by 40 Lewis alternating-current lamps of 500 watts. They are fed by separate high-pressure mains connected to the omnibus bars. The current is transformed in the base of the lamp-post, where small converters of special type are fixed. The pillars are of cast iron, fitted with ornamental brackets, from which the lamps suspend at a height of 18ft. above the ground. The whole plant was designed by Mr. Robert Hammond, who acted also as consulting engineer to the Corporation.

The Boston Electric Subway.—There are more suburban street railway lines converged into a few streets in Boston (Mass.), it is said, than are to be found in any other city in the States, and the problem of disposing of this enormous traffic was an intricate one, which was made more difficult by the narrowness of the streets. To dispose of this traffic a subway scheme has been adopted. The idea is that by having a tunnel devoted to the cars alone, and free from all interference by vehicles or pedestrians, schedule time will be made by the cars, which can naturally be run at much higher speed than on a crowded street. The general character of the subway differs from the type of tunnel hitherto employed for such structures. It is an object to have it near the surface, and to have it independent of lateral ground support, in the sense that it can stand by itself, if earth is removed from about it. This makes it secure from disturbance by excavations in the street. Hence, for the top, steel beams, with brick or concrete arches turned between them, are employed. For the bottom, two inverts of brick or concrete are to be used, the side walls rising from which are of masonry. A central row of pillars supporting a longitudinal girder is provided to support the centre of the roof in the four-track structure. The entire structure is to be made as waterproof as possible, and electric pumps are to be installed for the drainage of water that may collect in the sumps. Its standard height is 14ft., its standard width for two tracks is 24ft., and for four tracks 48ft. This will bring the top of the rail 17ft. below the surface of the street level, giving a descent of 16ft. for the passenger—a descent less than the average ascent required by the New York Elevated Railway system. The stations are all to be underground, and only the stairways will be seen above ground. There will be about five miles of single track. A special lighting plant will furnish electric lights for the entire length of the tunnel, the power being entirely distinct from that for running the cars. These will be incandescent lights carried on brackets. For ventilating the subway large electric fans will be used, discharging the air through ducts. Work is now in progress on the first section. The entire operations are in the hands of the Boston Transit Commission, which consists of five members, and which has power to establish rentals for the use of the structure by the street railway companies when completed. To force the companies to use the subway, the Commission is empowered to remove the tracks from the streets above the subway after its completion. The work will be done by the City and State authorities, and the expense is to be borne from a fund furnished by the city treasurer from the sale of bonds, and the public is to be freed by the rentals from extra taxation. The Commission will repave the streets, move sewers or pipes, strengthen foundations and conduct the entire work of construction, having also the management of the structure in charge, after completion.

Current Electrical Science.—The *Philosophical Magazine* contains a Paper by Dr. L. T. More, investigating the true causes of the change of length in soft iron bars produced by MAGNETISATION. It appears that there is a contractive force which opposes (unsuccessfully) the lengthening due to the new orientation of the molecules. The net effect is a gradual elongation, which becomes more and more rapid, and reaches a maximum at a field intensity of 1,200, and then suddenly falls. Hardening the wire diminishes the elongation, and the maximum sets in sooner. Stretching has the same effect; but allowance must be made for a change in elasticity produced by magnetisation. There is a thoughtful article by Dr. Johnstone Stoney on the kinetic theory of gases, of which we reprint an abstract this week. He shows how the vast multitude of molecular events, in an almost infinitesimal time, affords opportunity for accomplishing work which requires rare collocations of conditions. The future development of physical science will require more pioneers among the arcana of nature like Dr. Stoney.——Wiedemann's *Beiblätter*, No. 9, contains some capital abstracts of inaccessible electrical papers. There is a new form of ELECTRIC MACHINE by F. Busch, consisting of a paper band travelling round rollers and rubbed by rabbit skin, giving sparks 20cm. long! Two Russian physicists, with unprintable names, give their experiences of currents produced by water trickling through earthy material, and build a theory of EARTH CURRENTS upon their results. A. Abt describes the process of MAGNETISATION BY RUPTURE of iron bars. A characteristic German Paper by Prof. Ostwald is also abstracted, in which he explains the action of mind upon matter as something in the nature of catalysis. ——Our new English abstracts of physical papers, published by the Physical Society, form a perfect mine of electrical science. Among abstracts of comparatively inaccessible electrical Papers we notice one of M. Blondel's experiments with ALTERNATE CURRENT ARCS, in which he discovered a slight lag of the current behind the potential difference. This he attributes to a thermo-electromotive force produced at the positive carbon when at the temperature of volatilisation.——In the *American Journal of Science*, Dr. M. I. Pupin, in the first of a series of "Studies in the Electromagnetic Theory," discusses in an admirably clear manner the exact position of the law of ELECTRO-MAGNETIC FLUX in Maxwell's theory, and promises a more general form of this law. Dr. Pupin evidently intends to fight like another Heaviside, but without Mr. Heaviside's weapons, and 4π's are ominously frequent.

ELECTROMAGNETIC THEORY.—LXXVI.*

BY OLIVER HEAVISIDE.

(*Continued from page 741.*)

§ 298. When a cable is earthed at its ends the type of the normal function for the potential is $\sin sx$, vanishing terminally, s being fixed by $\sin sl = 0$. Left to itself, a distribution of potential of this type becomes reduced to $\sin sx \cdot \epsilon^{pt}$ at time t later, p being negative, fixed by $RSp = -s^2$. If the ends are both insulated, the normal function is $\cos sx$ for the potential, but with the same series of values of s, with the addition of a zero value, making 1 a special normal function. The roots of the determinantal equation are equally spaced.

Now, if one end be earthed and the other insulated, the normal functions are $\sin sx$ or $\cos sx$, as the case may be, with $sl = (n - \frac{1}{2})\pi$, n being integral. The roots of the determinantal equation are equally spaced in this case also.

In all other cases whatsoever, so far as I know, of real practical problems, the series of s's in the general normal function $\cos sx + a \sin sx$, where a is a constant, which are permissible and necessary in order that real and practical terminal conditions may be satisfied, differ from those given by $\sin sl = 0$ or $\cos sl = 0$, and are unequally spaced. It does not seem to be possible for any two arrangements of real condensers, resistances, and coils, acting at the terminals, to act in concert in such a way as to bring the determinantal equation back to the original simple type. It is perhaps for this reason, or rather for similar reasons in other physical problems involving Fourier series, that it has apparently escaped notice that Fourier's theorem, in which the s in the normal functions is $n\pi x/l$, n being integral, does not uniquely determine expansions of functions. It is, indeed, said to do so, but that is another story. It seems natural, for the above-stated reason, that mathematical physicists should not come across exceptions. On the other hand, pure mathematicians would, perhaps, not arrive at them, owing to the peculiar way they have of regarding the subject of the expansion of functions. They would be concerned with professedly rigorous proofs of Fourier's theorem, and of the convergency, rather than with the discovery of exceptions.

Guided, however, by physical ideas, though applied to entirely unpractical arrangements, involving instability, to be produced by latent impressed forces, set going by the real electrical mechanism, it is quite easy to adjust matters so that the terminal arrangement at one end of the cable shall combine with that at the other in such a way as to bring the roots of the determinantal equation back to the original simple kind. We come back to $sl = n\pi$, or $(n - \frac{1}{2})\pi$, with, however, the important and essential fact that there are extra normal functions of an abnormal kind. And so we come to violations of Fourier's theorem regarded as a unique expansion.

Thus, equation (85) shows the potential at x on the right side of y, due to Q initially at y, subject to the terminal conditions $V = -Z_0C$ at A, and $V = Z_1C$ at B. We may write it

$$V_1 = \frac{(Z_0 s\cos + R\sin)sy \cdot (Z_1 s\cos + R\sin)s(l-x)}{(Z_0Z_1s^2 - R^2)\sin sl + Rs(Z_0 + Z_1)\cos sl}\frac{sQ}{S}. \qquad (100)$$

In general, with practical resistance operators, the denominator only vanishes by the sum of the terms in it vanishing; then we have the determinantal equation (75), with unequally spaced roots, save in the limiting cases of terminal earth or disconnection.

But let $$Z_0 + Z_1 = 0. \qquad (101)$$
Then $$(Z_0Z_1s^2 - R^2)\sin sl = 0 \qquad (102)$$
is the determinantal equation. So $\sin sl = 0$, giving $sl = n\pi$, n being integral; and also,

$$Z_0^2 q^2 = R^2, \qquad (103)$$

where $q^2 = -s^2 = RSp$. Here, when Z_0 is a real resistance operator, the left member is an odd function of p. So there is an odd number of extra special normal functions.

Thus, in case of a resistance R_0 at A, we get

$$R^2 = R_0^2 RSp, \qquad (104)$$

showing one root, positive. In case of a condenser at A, or $Z_0 = -(S_0p)^{-1}$, we get

$$R^2 S_0^2 p = RS; \qquad (105)$$

again one root, positive. In case of a coil at A, with $Z_0 = R_0 + L_0 p$, we get

$$R^2 = (R_0 + L_0 p)^2 RSp. \qquad (106)$$

There are now three roots, and three extra normal functions. But two of them combine to make an oscillatory function. In general, the number of extras is unlimited. The physical interpretation will be considered a little later.

If, instead of (101) as the fundamental relation connecting the Z's, we substitute

$$Z_0Z_1s^2 = R^2, \quad \text{or} \quad Z_1 = -\frac{R^2}{q^2 Z_0}, \qquad (107)$$

the determinantal equation becomes

$$\left(Z_0 - \frac{R^2}{q^2 Z_0}\right)\cos sl = 0. \qquad (108)$$

So $\cos sl = 0$, or $sl = (n - \frac{1}{2})\pi$ for the regulars, just as if one end of the cable were earthed and the other insulated; and, in addition,

$$Z_0^2 q^2 = R^2 \qquad (109)$$

for the extras. So, with the same Z_0, there are the same extras as in the former case. But now, if Z_0 is a resistance, Z_1 is a negative permittance, and if Z_0 is a permittance, Z_1 is a negative resistance.

§ 299. We cannot consider both cases at once very well. Therefore first examine the case $Z_0 = -Z_1$. Equation (100) reduces to

$$V_1 = \frac{(R\sin + Z_0 s\cos)sy \cdot (R\sin - Z_0 s\cos)s(l-x)}{(Z_0^2 q^2 - R^2)\sin sl}\frac{sQ}{S}. \qquad (110)$$

Apply the expansion theorem. This had better be done separately for the regulars and the extras. Say $V = v_1 + v_2$, where v_1 is for the regulars, and v_2 for the extras. Then, working as in many previous cases, we find

$$v_1 = \frac{Q}{Sl} + \frac{2Q}{Sl}\Sigma\frac{(R\sin + Z_0 s\cos)sy \cdot (R\sin + Z_0 s\cos)sx}{R^2 + Z_0^2 s^2}\epsilon^{pt}, \qquad (111)$$

where $sl = n\pi$. The outside term represents the mean potential—that is, $Q/(Sl + S_0^1 + S_1^1)$, where S_0^1 and S_1^1 are the effective terminal permittances, which, however, cancel one another. But the outside term is only required when the terminal resistance is infinite at A, or $x = 0$.

For the extra terms, we may transform (110) to

$$V_1 = \frac{(R\,\mathrm{shin} + Z_0 q\cosh)qy \cdot (R\,\mathrm{shin} - Z_0 q\cosh)q(l-x)}{(R^2 - Z_0^2 q^2)\,\mathrm{shin}\, ql}\frac{qQ}{S}, \qquad (112)$$

in which it is to be noted that the p's determine the normal systems. We have

$$p\frac{d}{dp}(Z_0^2 q^2 - R^2) = R^2\left(1 + \frac{2p}{Z_0}\frac{dZ_0}{dp}\right), \qquad (113)$$

when $R^2 = Z_0^2 q^2$. Hence, using (113), and putting $R = Z_0 q$ in the numerator of (112), it, so far as the extras are involved, expands to

$$v_2 = \frac{Q}{S}\Sigma\frac{q\epsilon^{q(x+y-l)}\epsilon^{pt}}{R\,\mathrm{shin}\, ql \cdot \left(1 + \frac{2p}{Z_0}\frac{dZ_0}{dp}\right)}, \qquad (114)$$

ranging over the roots of $Z_0^2 q^2 = R^2$.

Finally, as before said, $V = v_1 + v_2$ is the complete expansion. The unit impulsive function is got by dividing by Q/S, and omitting the time factor, making

$$u = \frac{1}{l} + \frac{2}{l}\Sigma\frac{(R\sin + Z_0 s\cos)sy \cdot (R\sin + Z_0 s\cos)sx}{R^2 + Z_0^2 s^2}$$
$$+ \Sigma\frac{q\epsilon^{q(x+y-l)}}{\mathrm{shin}\, ql \cdot \left(1 + \frac{2p}{Z_0}\frac{dZ_0}{dp}\right)}, \qquad (115)$$

where the extras are in the second line alone. Herein Z_0 may be any rational resistance operator. It follows that

$$f(x) = \int_0^l uf(y)\,dy \qquad (116)$$

is the expansion of an arbitrary function $f(x)$.

Equation (115) being general, has the failings as well as the merits of general results. But we can easily interpret specially simplified cases.

§ 300. The simplest case of all is that of a positive resistance at A, and an equal negative resistance (to be interpreted later) at B. There is but one extra, as per (104). Denote the extra q by h for distinctness. Then $h=R/R_0$, the reciprocal of the effective length of the terminal resistance R_0 in terms of the cable. Therefore, since $dZ_0/dp=0$,

$$u=\frac{h\epsilon^{h(x+y-l)}}{\sinh hl}+\frac{2}{l}\Sigma\frac{(h\sin+s\cos)sy\,.\,(h\sin+s\cos)sx}{h^2+s^2} \tag{117}$$

expresses the unit impulsive function.

Let $f(x)=1$ for example; that is, start with a uniform potential in the cable. Thus an easy integration gives us the following expansion:—

$$1=\frac{2\epsilon^{hx}}{1+\epsilon^{hl}}+\frac{2}{l}\Sigma\frac{h}{s}\frac{(h\sin+s\cos)sx}{h^2+s^2}(1-\cos sl), \tag{118}$$

where $sl=\pi$, 2π, 3π, &c., the terms with even multiples having zero coefficients. The introduction of the time factor to each normal function shows the result later as usual. The summational part ultimately vanishes. The outside extra term increases with the time.

We may write (118) thus, if sl is confined to the odd integers:—

$$\frac{2\epsilon^{hx}}{1+\epsilon^{hl}}=1-\frac{4}{l}\Sigma\frac{h^2\sin sx}{s(h^2+s^2)}-\frac{4}{l}\Sigma\frac{hs\cos sx}{s(h^2+s^2)}. \tag{119}$$

The function on the left side is apparently expanded in a Fourier series. But it is *not* a Fourier series in the ordinary sense. It absolutely violates the conditions settling the size of the coefficients according to Fourier's theorem. It is only one example in a million, however. It illustrates a property of the wonderful function ϵ^x.

We may verify (118) by the conjugate property of normal systems. This is an absolutely sound method, provided we have *all* the normal functions at command. One normal function is ϵ^{hx}, the type of the rest is $(h\sin+s\cos)sx$. That the extra one is conjugate to the rest we see thus:—

$$\int_0^l\epsilon^{hx}(h\sin+s\cos)sx\,.\,dx=\int_0\frac{d}{dx}(\epsilon^{hx}\sin sx)dx=0. \tag{120}$$

Also, if w_1 and w_2 denote any two of the regulars, we may verify that

$$\int_0^l w_1w_2dx=0. \tag{121}$$

If, therefore, we assume that

$$f(x)=1=A_0\epsilon^{hx}+\Sigma A_nw_n, \tag{122}$$

we can isolate any coefficient by quadratures. Thus

$$A_0=\frac{\int_0^l f(x)\epsilon^{hx}dx}{\int\epsilon^{2hx}dx}=\frac{2}{1+\epsilon^{hl}} \tag{123}$$

finds A_0, and any one of the rest is found by

$$A=\frac{\int_0^l wf(x)dx}{\int_0^l w^2dx}=\frac{2h}{sl(h^2+s^2)}(1-\cos sl). \tag{124}$$

Comparing with (118), we verify that result. The quantity h may be positive or negative. Changing its sign merely makes the positive and negative resistances change places. Between the two, with $h=0$, we have the case of terminal disconnection. The conjugate property may be readily applied to the unit impulsive function (117) itself, so as to verify that formula.

As regards the expansion of the left member of (119), if done according to Fourier's theorem, the physical assumption would be such as to make the normal systems be $\cos sx$ and $\sin sx$, and this would correspond to an entirely different state of things. Out of physics came the subject of expansion in normal functions. Unto physics should we return for fresh inspiration.

§ 301. The next simplest case is that of a terminal condenser. Say that $Z_0=(S_0p)^{-1}$ at A. There is but one extra q. Denoting it by h, its value is S/S_0. Also, by using the new Z_0 in (113), we see that the result is $-R^2$ instead of $+R^2$, as in the last case. So, by (111) and (114), we find that the new unit impulsive function is

$$u=\frac{1}{l}+\frac{2}{l}\Sigma\frac{(R\sin+Z_0s\cos)sy\,.\,(R\sin+Z_0s\cos)sx}{R^2+Z_0^2s^2}-h\frac{\epsilon^{h(x+y-l)}}{\sinh hl}, \tag{125}$$

where the extra function is in the second line. Here $sZ_0/R=-h/s$, and we may write (125) more simply,

$$u=\frac{1}{l}+\frac{2}{l}\Sigma\frac{(s\sin-h\cos)sy\,.\,(s\sin-h\cos)sx}{h^2+s^2}-\frac{h\epsilon^{(hx+y-l)}}{\sinh hl}. \tag{126}$$

Applying this u to the special initial state $f(x)=1$, we obtain

$$f(x)=1=1-\frac{2\epsilon^{hx}}{1+\epsilon^{hl}}+\frac{2}{l}\Sigma\frac{(s\sin-h\cos)sx}{h^2+s^2}(1-\cos sl), \tag{127}$$

which gives another expansion of ϵ^{hx} not conforming with Fourier's theorem. In (127) sl has the values π, 2π, 3π, &c.; and the coefficients of the terms belonging to 2π, 4π, &c., vanish as before. The formula fails at the terminals, on account o the condensers.

The normal functions are now ϵ^{hx}, the sole extra function, and an infinite series of the type $(s\sin-h\cos)sx$, including the case $s=0$, or a constant term. But to verify (127) by the conjugate property, we must take count of the terminal condensers. Thus, if

$$w=(s\sin-h\cos)sx \tag{128}$$

be taken as the normal function along the cable it must be supplemented by

$$w_0=-h,\qquad w_1=-h\cos sl, \tag{129}$$

at the terminals. Similarly, the normal function ϵ^{hx} must be supplemented by 1 at A and ϵ^{hl} at B. The mutual energy of ϵ^{hx}, &c., and w, &c., is therefore

$$S_0w_0+\int_0^l S\epsilon^{hx}w\,dx+S_1\epsilon^{hl}w_1, \tag{130}$$

which, by the previous two equations, may be seen to vanish, thus proving the independence of the system ϵ^{hx}, &c., and any one of the w systems.

Similarly, we may show that the mutual energy of two w systems is zero. That is,

$$0=S_0\underset{(x=0)}{w_mw_n}+\int_0^l Sw_mw_n\,dx+S_1\underset{(x=l)}{w_mw_n}, \tag{131}$$

if w_m and w_n are any two different regular normal functions. I have not done it, but have no reason to doubt it. Then, all the normal systems being proved to be independent, quadratures find the coefficients when we assume

$$f(x)=A_0+\Sigma A_nw_n+B\epsilon^{hx}. \tag{132}$$

But there are different ways of doing it, according to whether $f(x)$ is the complete initial state, or whether the condensers are initially charged as well. In the latter case, if V_0 and V_1 are their initial potentials, we find the coefficient of any normal system by forming the expression for the mutual energy of the initial state and the particular normal state, using (130) or (131) to isolate the coefficient. Thus

$$A_n=\frac{S_0V_0w_{0n}+\int_0^l Sw_nf(x)dx+S_1V_1w_{1n}}{S_0w_{0n}^2+\int_0^l Sw_n^2dx+S_1w_{1n}^2} \tag{133}$$

finds A_n, if w_{0n} and w_{1n} are the terminal values of w_n. And

$$B=\frac{S_0V_0+\int_0^l Sf(x)\epsilon^{hx}dx+S_1V_1\epsilon^{hl}}{S_0+\int_0^l S\epsilon^{2hx}dx+S_1\epsilon^{2hl}} \tag{134}$$

finds B. The formula for A_n also answers for A_0, if it be taken to mean the coefficient of $-h$, which is what w reduces to when $s=0$.

Now, in the case of (127), $f(x)$ alone is existent, and we must make V_0 and V_1 zero in (133), (134). Doing this, and developing the results, we shall arrive at (127), and verify it. We may also use (133) to obtain the effects due to V_0 and V_1. Initially we must have zero expansions—that is to say, expansions which represent zero, except at the terminals. To find the proper expansion to represent V in the cable due to the initial charge S_0V_0 of the real condenser at A, and

Digitized by Google

the charge S_1V_1 at B, put $f(x)=0$ in (133), (134), and evaluate. The results are

$$A=\frac{2}{l}\frac{V_1\cos sl - V_0}{s^2+h^2}, \quad A_0=\frac{V_0-V_1}{hl}, \quad B=2\frac{V_0-V_1\epsilon^{hl}}{1-\epsilon^{2hl}}, \quad (135)$$

to be used in (132). The result is therefore

$$0=2\frac{V_0-V_1\epsilon^{hl}}{1-\epsilon^{2hl}}\epsilon^{hx}+\frac{V_0-V_1}{hl}+\frac{2}{l}\Sigma(V_1\cos sl - V_0)\frac{(s\sin - h\cos)sx}{s^2+h^2}. \quad (136)$$

The 0 on the left side expresses $f(x)$, the potential of the cable everywhere, except at the terminals, where, on account of the condensers, special interpretation is needed.

If we assume $V_0=V_1$, the mean term disappears, and we reduce the last result to

$$0=\frac{2V_0\epsilon^{hx}}{1+\epsilon^{hl}}-\frac{2V_0}{l}\Sigma\frac{(s\sin - h\cos)sx}{s^2+h^2}(1-\cos sl), \quad (137)$$

where only the odd values of n in $s=n\pi/l$ are effective. This corroborates (127).

If we multiply (127) by V_0, it expresses V_0 all along the cable. Adding the result to (137), we obtain $1=1$. This is obvious by arithmetic. But it means more than that here—namely, that if the initial state is V_0 constant in the cable and both condensers as well it will remain constant, because there is nothing to disturb it.

§ 302. If we say that the equation to be obeyed at one end of the cable, say at B, is $V=R_1C$, and further say that R_1 is a positive constant, the most obvious interpretation is that R_1 is a mere resistance. The equation then asserts Ohm's law simply. But this is not necessarily the interpretation. What the equation asserts is that the ratio of V to C is positive and constant. There may therefore be any electrical arrangement that will produce this result. A distortionless circuit will do it, and in many ways. Electric and magnetic energy are then involved, either with or without waste of energy by conductive resistance. The distortionless circuit will behave to an impressed force precisely like a resistance.

Similarly, if we say that the terminal condition is $V=-R_1C$, where R_1 is still a positive constant, we do not assert that $-R_1$ stands for a negative resistance. That would make nonsense, according to the commonly understood electrical law. Any arrangement that will, when acted upon by an impressed voltage, compel the current to obey the law $V=-R_1C$, is what is implied by that equation of condition. We are not obliged to enter any further into detail as to how it is to be done. A source of energy is involved, of course, which, however, does not require any specialisation, since the resultant effect is embodied in the law.

To save circumlocution, it is obviously convenient to speak of a negative resistance, to be understood as above. Now put a positive resistance at one end of a cable, say at A, and an equal negative resistance at B, and let the cable be initially charged at one place, say with a charge Q at y. This charge instantly begins to spread, and raises the potentials at A and B slightly. There is, therefore, a current *from* the cable at A, but *into* the cable at B. The former is normal, the latter abnormal, due to the terminal resistance being negative at B. The B end of the cable therefore becomes charged faster than the A end, and the higher its potential is raised the stronger becomes the current into the cable. At the A end, on the other hand, where things are normal, the current due to the initial charge would first rise to a maximum and then fall slowly to zero. But the continuous entry of fresh charge at B alters matters. It spreads all along the cable, from B to A, raising the potential of the whole cable. The ultimate result, therefore, when the normal effects due to the initial charge have subsided, is a state of positive charge increasing continuously with the distance from the A end, and increasing continuously with the time. This is the meaning of the extra normal function ϵ^{hx} for the potential. The current to match is directed from B to A. Both are associated with the time factor ϵ^{pt}, where $p=h^2/RS$.

The equilibrium state of zero potential is accordingly unstable. An infinitesimal charge arriving at B is sufficient to disturb the equilibrium. Which way the current will set in at B will depend on the sign of the initial point charge. If V becomes positive current will enter the cable, and continue to do so. If negative, current will leave the cable at B, and the cable will become charged negatively.

An arbitrary initial state of electrification in the cable, left to itself, will in time either wholly disappear, or will be replaced by the distribution $\epsilon^{hx}\epsilon^{pt}\times$ constant. Equation (117) determines the behaviour fully, when applied to the initial state. An initial state of the type

$$w=(h\sin + s\cos)sx$$

subsides to equilibrium, as may be readily seen by its satisfying the abnormal terminal condition at B, the current and the potential having opposite signs. Similarly, the sum of any number of such distributions, of any sizes, will subside to equilibrium. But they cannot make up an arbitrary distribution, because the abnormal distribution is left out. An initial distribution of the type ϵ^{hx}, instead of subsiding, increases with the time. In order that no term of this sort should enter, the initial state must be specialised so as to exclude it. Thus, the first equation in (123) settles the coefficient of ϵ^{hx}. It is zero if the integral of the product of the initial state and ϵ^{hx} is zero. This is the case when the initial state is the sum of a number of systems of the regular type w. The simplest case, however, is to have two point charges, one positive, the other negative, with their sizes suited to their distances from B. Thus, if

$$Q_1\epsilon^{hy_1}+Q_2\epsilon^{hy_2}=0,$$

Q_1 and Q_2 being the charges, at y_1 and y_2 respectively, the expression for u in (117) shows that the abnormal term ϵ^{hx} does not exist.

After so much detail concerning this simple abnormal case, others of a similar character may be very briefly treated. As for why they are considered at all, an anecdote about Dr. Elliotson comes in useful. One of his students said he did not see the use of studying morbid physiology; it was so unnatural. The doctor told him he was a blockhead, adding, "It is only by the study of the morbid that the true conditions of health can be ascertained."

(To be continued.)

ELECTRIC TRAVELLING CRANES IN SHIPBUILDING.

A new departure in shipbuilding, calculated to have far-reaching developments, has recently been made by Messrs. Swan and Hunter, of Wallsend-on-Tyne. This consists in carrying on the operations of building beneath a structure provided with travelling cranes so arranged that material may be transported from end to end, overhead, and therefore in no way interfering with the movements of the workmen. This erection, which forms an imposing landmark, is about 500ft. in length, 68ft. wide in the clear between the side frames, and about 80ft. high, and is constructed entirely of steel. At the lower part horizontal girders are introduced to carry one end of the shores, and the lowest tier of these being about 10ft. from the ground level, enables the vessel to be adequately stayed without in any way interfering with free passage.

The most important use of this roof is, of course, to support the travelling cranes above referred to, which are carried on two tracks about 12ft. wide and 22ft. from the centre line of the roof on each side. As the employment of steam cranes at this elevation presented many objections, it was decided to adopt electric power, and for this purpose designs were invited from several of the leading electric crane makers, the design of Messrs. Clarke, Chapman and Co., of Gateshead, being finally adopted. We give illustrations of these (Figs. 1 and 2), showing the general features of their construction, also views taken (Figs. 3 and 4) from the roof showing them in position.

From these illustrations it will be seen that the cranes are suspended on the track, and have a clear run the whole length of the supporting roof. The upper part consists of a square frame formed of steel joists supporting a circular wheel path on which the jib turns, and which allows of a complete revolution being made. The length of the jib from the centre to the rope sheave at the end is 22ft., and a platform is provided on one side and at the end where the motor is placed, rendering

Digitized by Google

all parts of the crane accessible. The electric motor is placed at the back end so as to act as a counterpoise, and is capable of giving off 25 B.H.P. at a speed of 700 revolutions per minute. It is shunt wound, and is mounted on a sliding adjustable frame. The current is received through bare conductors fixed on insulators at each side of the crane road, and from the collectors passes to the main switch through contact rings in the upper frame. The various movements are obtained by belts, the reversing being by double clutches and mitre gear. The motor drives by two belts the main countershaft in the centre line of the upper frame, one giving a speed of 400, and the other a speed of 200 revolutions per minute to this shaft, from which all the other movements are derived, the travelling and slewing gear having two definite speeds, which may, however, be modified within certain limits by an adjustable resistance fixed on the jib near the operator,

As the cranes are suspended, great care has been necessary in their construction, and the employment of various safety devices renders them as safe as possible. In the upper frame, to prevent accident caused by the failure of a wheel or shaft, four brackets are provided, which are fixed to the frame very near to the rails, so that under no circumstances could the crane fall more than about ½in.

As the roof is built to a gradient corresponding to that of the ways—viz., 1 in 50—means had also to be provided to render it impossible for the crane to run away; this is accomplished by an electric brake on the upper shaft, which is put in operation by a small switch placed conveniently to the crane man, and which stops the motion in a short distance when descending at the high speed (300ft. per minute) at which the crane travels.

For the travelling motion two mitre wheels are mounted on the central countershaft, having between them a double coupling which can engage with either; these gear into a corresponding wheel on a vertical shaft, which is, of course, in the centre line of the upper frame and the centre of rotation of the jib. A longitudinal shaft on the top serves to transmit the motion by means of two worms and worm wheels to the transverse shafts at each end, on which are fixed the travelling wheels. Two distinct speeds are obtained, 300ft. and 150ft. per minute respectively, though these can, of course—as with the other motions—be modified to a considerable extent by means of the variable resistance. The weight of the crane being about 14 tons, it will be seen that the work done in merely lifting it with its full load of 3 tons up this incline of 1 in 50 is 6 H.P., without allowing for friction in tractive effort.

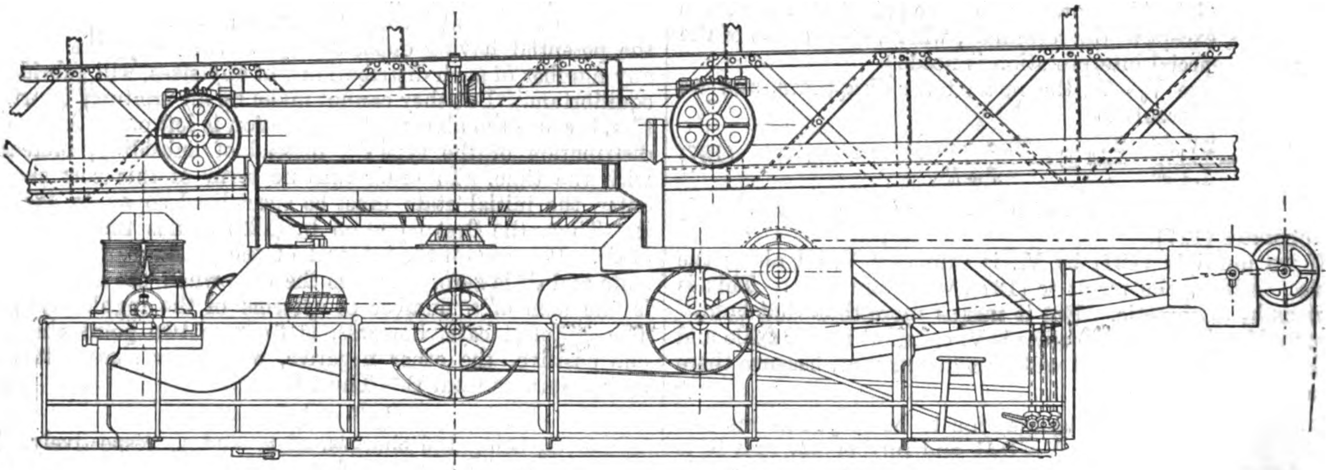

Fig. 1.—Elevation of Crane.

The circular motion of the jib is obtained by a pinion gearing into an internal wheel in the upper frame, and the circumferential velocity at the extremity is, normally, 150ft. and 75ft. per minute.

The hoisting gear is all placed in the jib, and consists of a drum grooved to receive the wire rope, and having secured to it a worm wheel gearing into a worm, which can be driven in either direction by suitable gear. There are two different speeds in this gear independent of those obtained from the countershaft, thus giving four speeds of lift—namely, 100, 65, 50 and 32·5ft. per minute. The two higher speeds are used for light weights up to 30cwts., the slower speeds for lifts exceeding this.

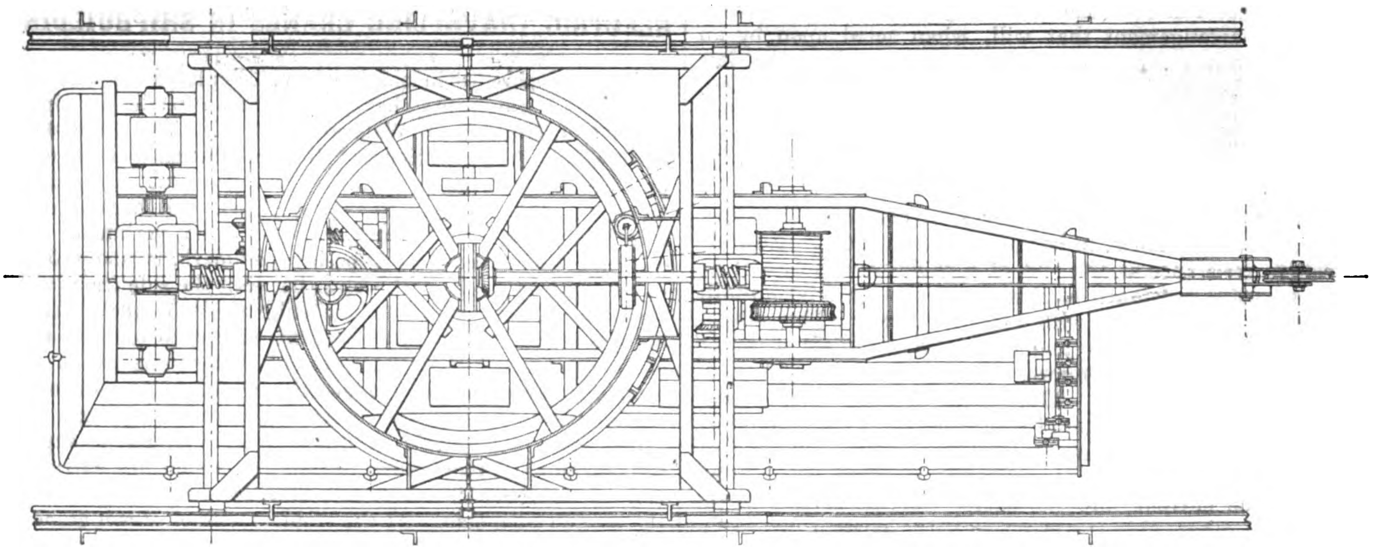

Fig. 2.—Plan of Crane.

An important consideration in this connection was that of providing means whereby the crane could not be overloaded or strained, as, for instance, by a plate catching on the underside of the ship framing. To meet this difficulty, the sheave carrying the wire rope is mounted at the end of a lever having its fulcrum near the sheave. The gudgeon pin is supported on

Digitized by Google

a spring, and the sides of the frame are slotted, so as to allow a vertical displacement of about 3in. (*see* Fig. 1). This, therefore, allows the rope sheave to descend 3in. in case of the rope being held in any way. The long end of the lever is held by a spring which can be adjusted to suit any weight the crane is intended to deal with, and should this be exceeded the lever rises, and by so doing operates a trigger switch, which cuts off the current and so stops the motor, and at the same time releases the striking gear bar and throws the belt on the loose pulley. These operations take place so rapidly that it is impossible to strain the crane or to lift more than the weight for which the spring is adjusted.

The switches and levers controlling the several motions are all placed conveniently to the crane man, and sufficient experience has now been gained to prove the satisfactory working of these cranes, and to demonstrate that a decided step forward has been taken in the direction of rapidity and economy in connection with shipbuilding.

In the power house there are at present two shunt-wound dynamos, each capable of generating 60 kilowatts, the speed being 550 revolutions per minute, and an exciter, which also serves to charge the accumulators used for lighting the offices. The dynamos are driven by a Robey compound engine of about 200 H.P. It is intended to have two more generators of the size given above, provision having been made in the foundation to receive them. The generators, exciter, and switchboard were supplied by Messrs. Clarke, Chapman and Co., and are in every respect worthy of that firm.

THE INFLUENCE OF THE SHAPE OF THE E.M.F. CURVE UPON THE IRON LOSSES OF ALTERNATING CURRENT TRANSFORMERS.

BY CLARENCE P. FELDMANN.

The step from the legendary ground of the pure sine curve to the real shape of the E.M.F. curve introduces complications, but allows conclusions upon the real working conditions of a transformer. Mr. A. Hill has shown, in Vol. XXXIV. of this journal, how to trace the idle current of a transformer whose hysteresis curve is known. I have gone a step further, and have found a graphical method of showing the differences between the iron losses for peaked and flat curves of E.M.F.

When trying to introduce the real shape of the E.M.F., the first difficulty is offered by the fact that not only the E.M.F., but also the curve of magnetism contains wrinkles due to the existence of the higher harmonics. The iron is thus carried through hysteresis cycles with loops, and as these loops are passed with 3, 5, . . . times the velocity as the main cycle, they must obviously change their position with regard to the main cycle.

This difficulty is overcome as soon as not only the curve of E.M.F., but also that of the corresponding magnetism, is resolved into its components, and treated in Mr. Hill's way for finding the idle current. Each component, e_1, e_3, e_5 of this E.M.F. E is a sine curve; its corresponding curve of magnetism is therefore also a sine curve, whose amplitude,

Digitized by Google

n_1, n_3, n_5. corresponds to the maximum value of a hysteresis cycle passed with the velocities p, $3p$, $5p$ . . . respectively. If, now, the behaviour of iron used is known for all the cycles whose maximum values of B are $\frac{n_1}{s}$, $\frac{n_3}{s}$, $\frac{n_5}{s}$ . . . respectively, s being the section of the iron core, the components i_1, i_3, i_5 . . . of the total idle current J_1 may be found. These components are no longer sine waves, as they are again made up of a wattless and a watt-component, but show the characteristic deformation due to the variation of the permeability. They would be altered if eddy currents could be considered, but to avoid too great complications these losses and alterations have been left out of account.

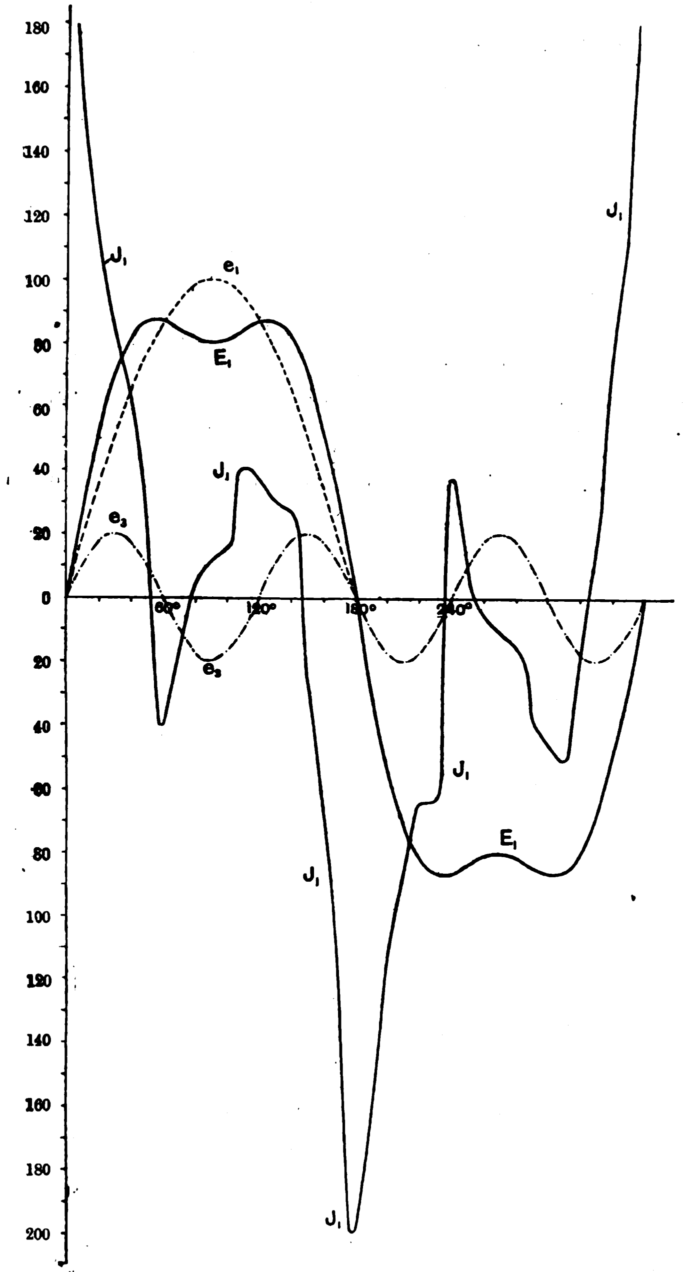

Fig. 1.—Flat Curve of E.M.F., Components of E.M.F., and Total Idle Current.

By gathering all the idle currents i_1, i_3, i_5, whose frequency is p, $3p$, $5p$ respectively, the total idle current J_1 may be obtained—a largely deformed curve with a rather high number of smaller ripples. This curve is displaced in phase with regard to the curve of the total E.M.F. E; but though these curves are both largely deformed, the product of two of their corresponding values gives the power spent in the core of the transformer at the moment regarded, and the arithmetic mean of all these momentaneous values of the power gives the mean value sought for. This value might be found by drawing and planimetering the curve of the power spent, or by multiplying corresponding ordinates of the J_1 and E curve and working out their mean arithmetic value.

Proceeding in this way with the two excessively deformed curves,

$$E_1 = 100 \sin pt + 20 \sin 3pt = e_1 + e_3 \text{ (Fig. 1)},$$

$$\text{and } E_1' = 100 \sin pt - 20 \sin 3pt = e_1' - e_3' \text{ (Fig. 2)}.$$

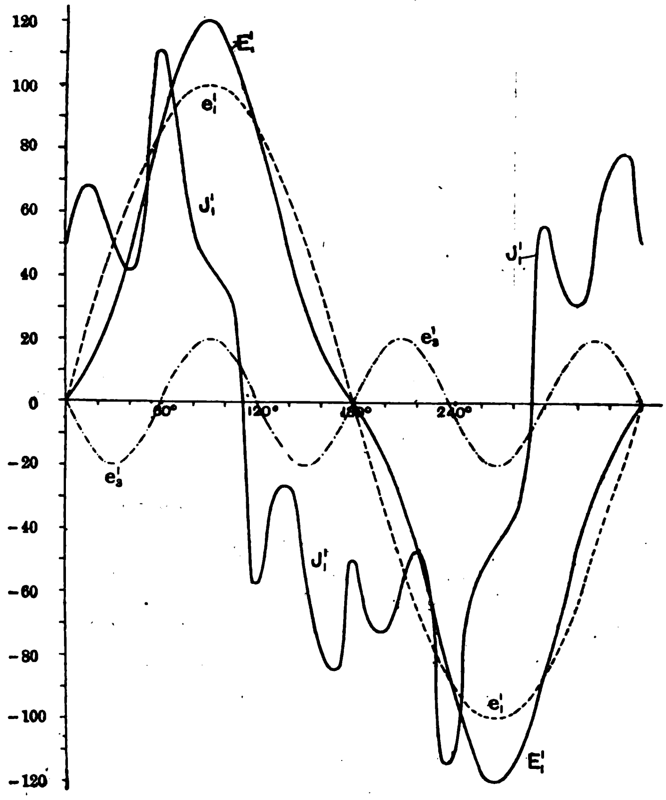

Fig. 2.—Peaked E.M.F., Components of E.M.F., and Total Idle Current.

I first obtained the components n_1, n_3 (Fig. 5) and n_1', n_3' (Fig. 6) of the curves of magnetism N and N_1', by deriving respectively the components e_1, e_3 and e_1', e_3'. Then two modified hysteresis curves (Figs. 3 and 4) were drawn whose

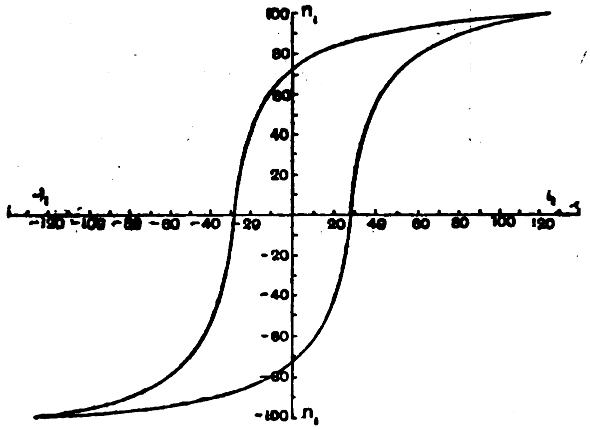

Fig. 3.—Hysteresis Curve for n_1.

maximum ordinates corresponded to $n_1 = n_1'$ and $n_3 = -n_3'$ and whose abscissæ gave directly the idle currents $i_1 = i_1'$ and $i_3 = -i_3'$ (Figs. 3 and 4). The total idle currents J and J_1', which are the sums of i_1 and i_3, i_1' and i_3', were then introduced in Figs. 1 and 2 and from them and the curves of E.M.F. E_1 and E_1', the energy spent in the iron was calculated and found to be, in arbitrary units: 653 for the flat E.M.F. (Fig. 1) and 622·5 for the peaked E.M.F. (Fig. 2), giving a difference of 4·8 per cent. in favour of the latter. These values are directly comparable, as the $\sqrt{\text{mean square}}$ of the two E.M.F.'s, as given

Digitized by Google

by a Cardew voltmeter, viz., $\sqrt{e_1^2 + e_3^2}$, and the hysteresis curves, are the same. This result has been calculated, without the use of high mathematics, on p. 430 of my book,* and has been verified by Charles P. Steinmetz in the discussion upon the true or imaginary value of the sine curve.

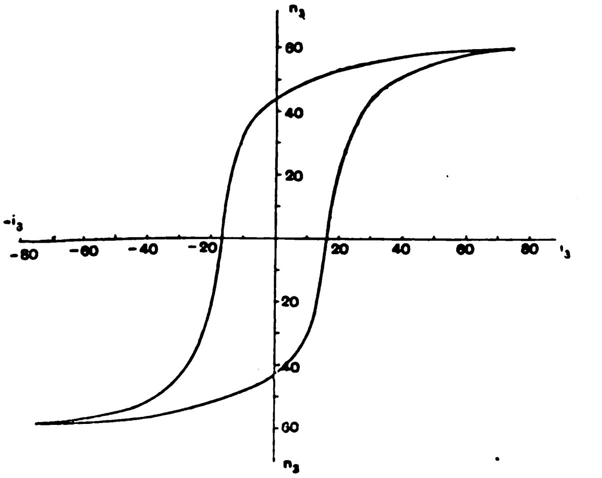

FIG. 4.—Hysteresis Curve for n_3.

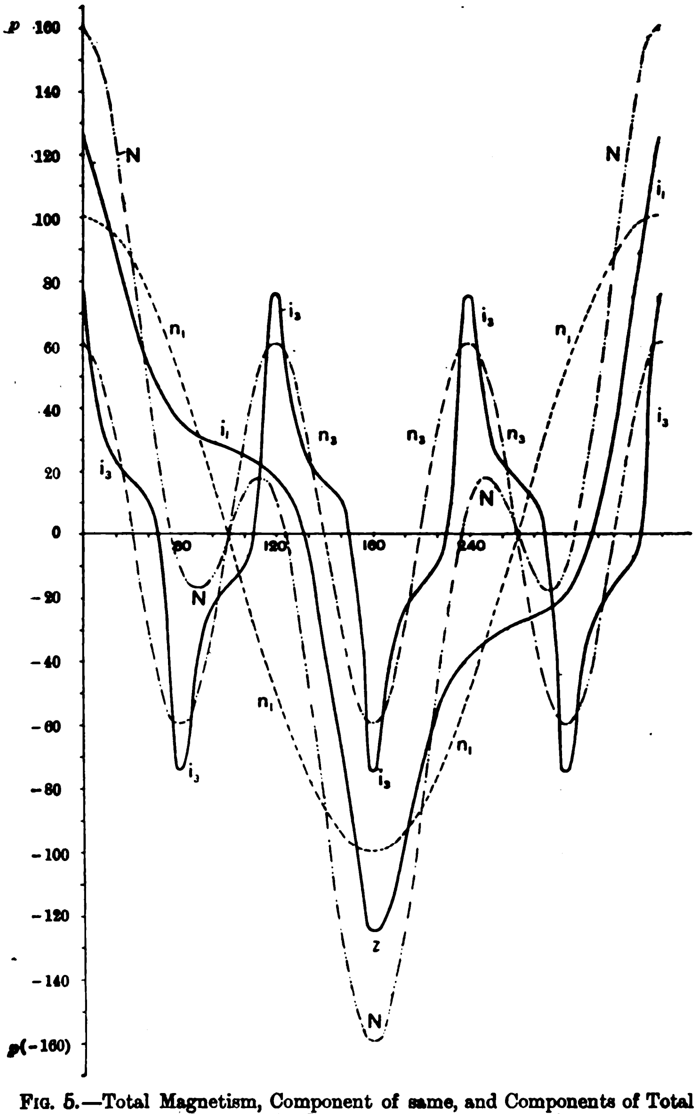

FIG. 5.—Total Magnetism, Component of same, and Components of Total Idle Currents for Flat Curve of E.M.F., Fig. 1.

A new result is obtained if the method described is carried a little further. The curve and components of the magnetism have been obtained by finding graphically the change of the E.M.F. curves. If, now, the change of the curves (N) and components (n_1, n_3) of the magnetism is evaluated, the curves

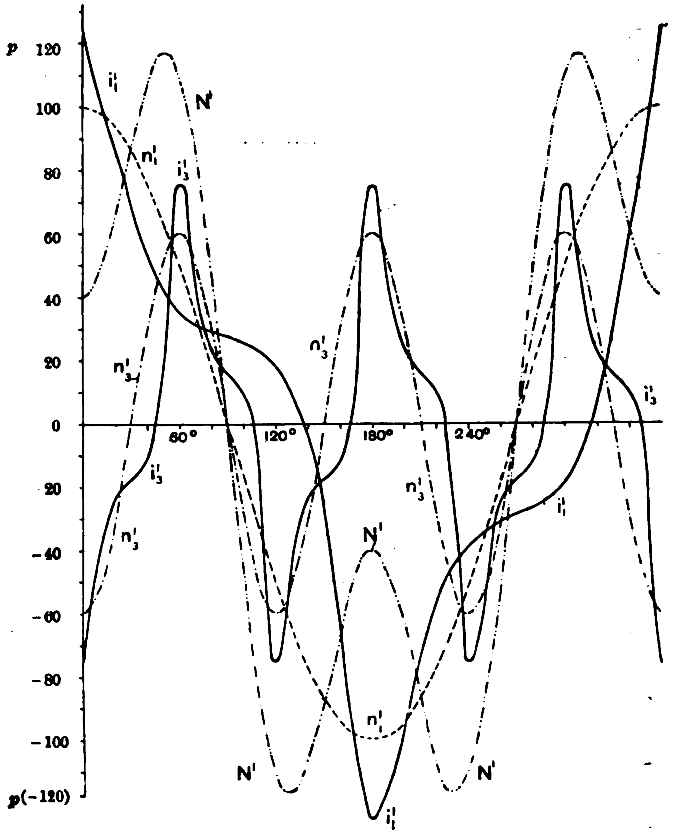

FIG. 6.—Curve and Components of Magnetism and Idle Currents for Peaked Curve of E.M.F., Fig. 1.

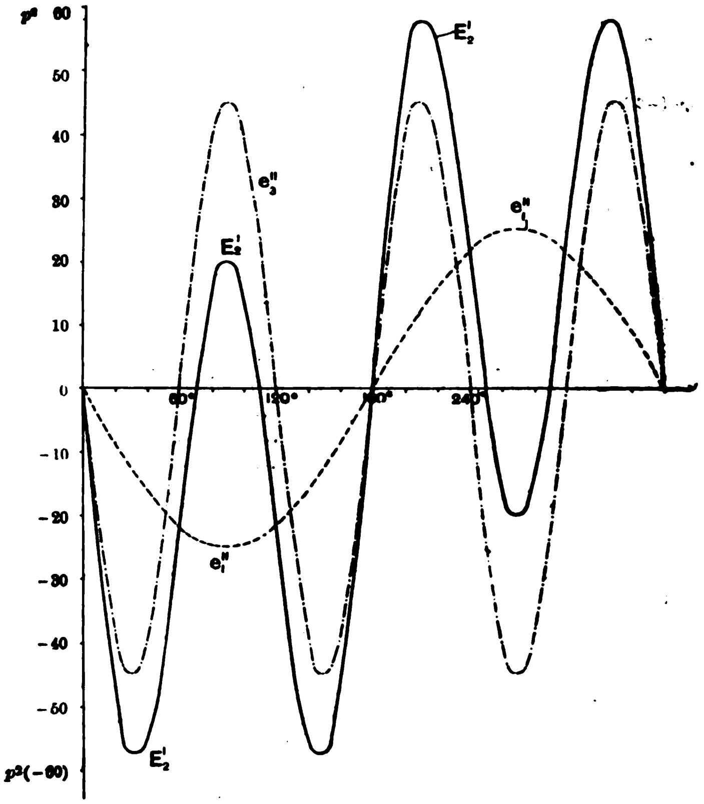

FIG. 7.—Secondary E.M.F. and Components, corresponding to the Primary E.M.F., Fig. 2.

and components of the secondary E.M.F. are obtained. They are represented in Figs. 7 and 8, and clearly show the increased influence of the higher harmonic. If the transformer is supposed to convert in the ratio 1 : 1, and so show but negligible waste field, the total idle current and its components must have

* "Prüfung, Wirkungsweise und Bereichnung der Wechselstrom Transformatoren." (Leipzig: O. Leiner.)

Digitized by Google

the same values and opposite phases as before. By multiplying corresponding values of current and secondary E.M.F., and taking the mean value, it may easily be found that with the increased influence of the expression with $3p$ the iron core loss

For the formerly peaked curve has been diminished from 622·5 to 615·5 ...... } In the same arbitrary units as before.
For the formerly flat curve has been increased from 653 to 678 .... }

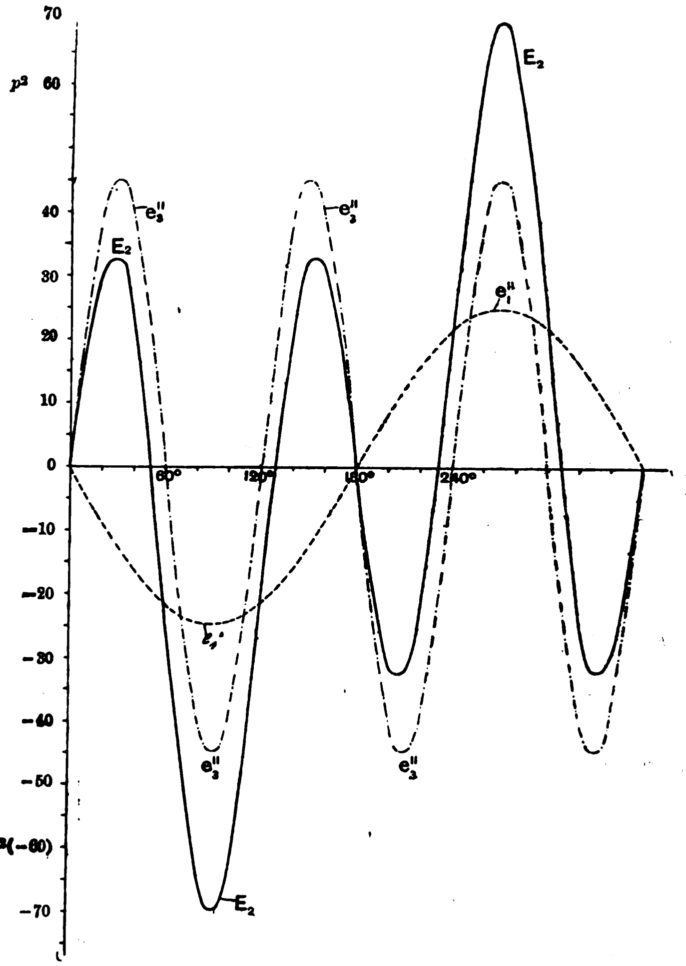

Fig. 8.—Secondary E.M.F. and Components, corresponding to the Primary E.M.F. Fig. 1.

This note has been caused by a letter of Mr. L. Neustadt, of Budapest, who told me in August of last year that one and the same transformer measured at 105 volts with differently-shaped E.M.F.'s, showed the following iron losses :—

With $p = 40$ ∾ and primary current...301 watts } For peaked
With $p = 40$ ∾ and secondary „ ...257 „ } E.M.F.
With $p = 42$ ∾ and primary current...262 „ } For flat
With $p = 42$ ∾ and secondary „ ...296 „ } E.M.F.

These numbers are not directly comparable, because of the different periodicity. But they clearly show the influence of transformation. The method described is, of course, only an approximate one.

AN APPARATUS FOR THE DEMONSTRATION OF THE DEVELOPMENT OF HEAT IN WIRES BY ELECTRIC OSCILLATIONS.*

BY IGNAZ KLEMENCIC.

The theoretical investigation of electrical oscillations tells us that for these the distribution of current over the section of a conductor is different to that which obtains for a steady current. In the case of oscillations, the density of the current is largest near the surface and smallest near the centre of the wire; in fact, with high-frequency oscillations the current is confined to a thin layer at the surface, the thickness of which depends, however, on the nature of the material. In consequence of this peculiar distribution of current, the resistances of wires are different for oscillations and for steady currents. The development of heat in a conductor, when a current is passing through, is fixed by its resistance. In two similar wires, when a steady current is passing through them, the ratios of the heat developed is given by the ratio of their specific resistances. But owing to the circumstances mentioned above the ratio of the developed heats in the case, oscillatory currents will be a different one. The experimental investigations of Bjerknes and of the writer on the absorption of energy in different wires traversed by electrical oscillations have at least qualitatively confirmed theory. It appeared to me desirable to devise an apparatus which would show in a convenient way the ratio of the heat developed by a steady current and by electric oscillations, and which would also be suitable for lecture experiments, and in the following note I propose to describe some apparatus which should fulfil these conditions, at least in a provisional way.

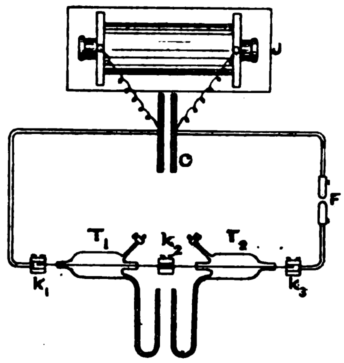

Fig. 1.

The apparatus is shown in Fig. 1. It consists principally of two air thermometers, T_1 and T_2, with the wires to be experimented upon enclosed within them, of a condenser C, and the spark-gap F. Riess, as is well known, has already enclosed a fine wire in an air thermometer for the purpose of studying the development of heat caused by the discharge of a Leyden jar. In this case the air thermometer had to be of a different shape, and the use of a very fine heating wire is out of the question. Fig. 2 shows the thermometer used, half size; *a b* and *c d* are copper wires, 3 mm. thick, to which, between *b* and *c*, the experimental wire, about 0·4 mm. thick, is soldered.) The copper wires are cemented into the

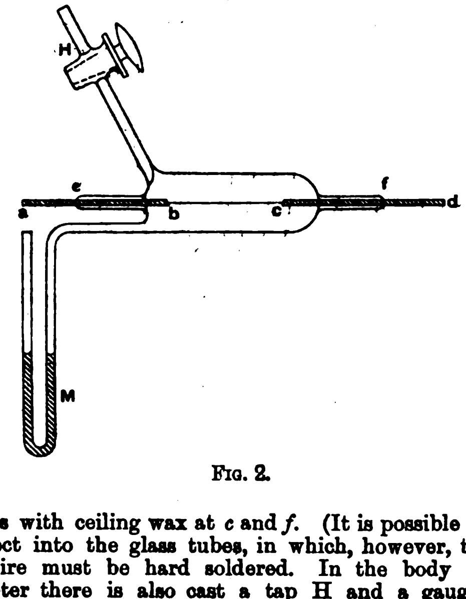

Fig. 2.

glass tubes with ceiling wax at *c* and *f*. (It is possible to cast the same direct into the glass tubes, in which, however, the experimental wire must be hard soldered. In the body of the air thermometer there is also cast a tap H and a gauge tube M. As gauge, liquid coloured alcohol can be used. Two of these air thermometers are used, containing experimental wires of equal length and thickness but of different materials. In demonstrating the development of heat in the wires, one cannot try to show that the resistance for electric oscillations is larger than for a steady current, but one must be satisfied with proving that the ratio of the resistances as judged by the development of heat in the two wires is different for electric oscillations and for steady currents. The two air thermometers are fixed by means of the copper wires to the terminals k_1, k_2, k_3. These are so arranged as to permit of an easy exchange of the air thermometers. The terminal k_1 is connected by a copper wire 3mm. thick to one side of the

* From *Wied. Ann.*, No. 4, 1895.

Digitized by Google

condenser C, and k_3 by a similar wire, after passing the spark gap, which is about 3mm., to the other side.

The condenser consists of test tubes filled with mercury, the inner having a diameter of 18mm. A Leyden jar or a Franklin plane would serve the same purpose, only then the connection of the conductor with the plates has to be a fixed one. The two small cylinders between which the spark takes place are rounded at the sparking end and fixed into a metal shell, which again rests on glass supports. The length of the spark gap is adjustable, the most suitable distance being about 3 mm. All parts of the apparatus are fixed on a board and the terminals of the secondary of an induction coil J have only to be connected to the plates of the condenser and the apparatus is complete. It should be mentioned that the gauge glasses of the air thermometer must be vertical, and the conductor circuit horizontally arranged. The Leyden is charged by the induction coil, and as soon as the potential reaches a certain height a spark passes at F. The electricity of the two plates is then equilibrated by an oscillatory discharge, as the experiments of Fedderson and others show. The charge and discharge is repeated several times a second, and a distinct development of heat in the experimental wires is noticed, the liquid in the open ends of the gauge glasses rising. The duration of the oscillations depends, as is known, on the capacity and self-induction of the circuit. Under the conditions which obtained it was very likely less than 10^{-6}sec.

The experiments are carried out as follows :—A steady current from a battery (with a suitable resistance in its circuit) is sent through the experimental wires and the heights of the gauge liquids is observed. The ratio of these heights are the same as the resistances, or, if the experimental wires are of equal length and thickness, as the specific resistances of the wire. The cocks of the air thermometer are now opened for a moment to equalise the pressure, and then the induction coil is excited. The wires are now heated by electric oscillations, and the heights of the gauge columns are different from those observed with the steady current. Especially noticeable is this when an iron wire and a German silver or platinum-iridium wire are used. The following are a few results obtained with two pairs of experimental wires :—

I. German silver and brass wire 6cm. long and 0·37mm. in diameter ; ohmic resistance, brass wire = 0 042, German-silver wire = 0·145. The gauge column rose, with a steady current of 1 ampere, 13mm. in the air thermometer containing the brass wire, and 48mm. with the German-silver wire. When oscillations were taking place the rise was 12mm. and 26mm. respectively. The ratio of the heights for a steady current is 3·7, and is nearly equal to the ratio of the resistances ; for the oscillations it is 2·2. This corresponds with what theory would lead us to expect.

II. Iron and platinum-iridium wires, each 3cm. long and 0·4mm. in diameter ; ohmic resistance, platinum-iridium wire = 0·068, iron wire = 0·037. Rise of the gauge column with steady iron wire = 13mm., platinum-iridium wire = 23mm. When oscillations are going on, iron wire = 35mm., platinum iridium wire = 15mm. The ratio of the rises of the gauge column in the case of a steady current is 1·8, the same as the ratio of the resistances ; but in the case of oscillatory currents the rise is greater for iron than platinum-iridium wire, since the resistance to electric oscillations increases very much with the magnetisibility of the wire.

In connection with the above figures it must be remarked that the absolute values are not great, and to make the relative heat development visible to a larger audience the figures of the two gauge glasses should be thrown into a screen. In using a more powerful source of energy—for instance, an alternator—in connection with a transformer instead of an induction coil, greater rises could be obtained, and the gauge tubes could be lengthened. To protect the air thermometers from illumination it is a good thing to cover them up with paper. Although the apparatus in its present form enables one very well to demonstrate the differences in the heat developed in wires by a steady current and by electric oscillations, there is room for improvements.

PHENOMENA AND RESEARCH.*

BY G. JOHNSTONE STONEY, M.A., D.SC.

Science may be defined as the investigation of how Nature works, of how and why events in Nature occur. This investigation is best carried on by employing the Physical Hypothesis, viz , that the objects of Nature act on one another, either directly (action at a distance), or through intervening media (which by many is supposed to be an essentially different kind of action). Now, the objects of Nature, in the more strict sense of that phrase, are syntheta of human perceptions and ultra-perceptions ; and syntheta of perceptions cannot be what really act. Nevertheless, it is eminently useful to carry on our investigation under the physical hypothesis that it is they which act, and to confine our efforts to tracing out what effects this action must be supposed capable of producing, and under what laws it must operate, in order that it may account for what occurs in Nature. This, however, is felt by many persons to be too abstract an attitude of mind ; and to satisfy them, and create the plausibility which they demand, by relieving the fundamental conceptions of what is oppressively felt as the absurdity of supposing that syntheta of perceptions act, it is usual to supplement these syntheta by piling an aërial Pelion upon this solid Ossa, and by supposing that in addition to the *sensible object* which occupies any portion of space there is what is called *its material substance* occupying the same position, which, partly directly and partly by its motions, acts on other material substances (the ether being one of these material substances). According to this, which is the prevalent hypothesis among both scientific and non-scientific men, it is these substances which travel about through space ; and the sensible objects, which are what we see and feel are supposed to accompany them in their wanderings by reason of the way in which they, the substances, act (usually through intermediate material agencies) upon our organs of sense.*

This is the usual point of view ; but more careful thinkers will do well† to eschew this somewhat convenient, but by no means necessary, encumbrance upon the unadulterated process of physical investigation, which treats the sensible objects themselves, the bare syntheta of perceptions and ultra-perceptions, as though they were what brought about the changes that occur in Nature ; and which exclusively occupies itself in tracing out the laws that must, under this hypothesis, be in operation in order that the effects may be what they are.

Another and a very useful scaffolding, which helps us in building up our investigation, is the introduction of forces between the physical cause (which is always the vicinity of some natural object) and the effect to be attributed to it under the physical hypothesis. We are thus enabled to speak of the acceleration of a stone in its fall towards the earth either as being due to the neighbourhood of the earth, or as being caused by a force of gravitation which acts on it, which force is, in its turn, regarded as brought into existence by the proximity of the earth to the stone. The introduction of this piece of intermediate scaffolding is of great service—

1. Because the force can be represented by a line whose length accurately represents the intensity, and whose direction accurately represents the direction of the effect upon the stone of the vicinity of the earth ;

2. Because the same effect upon the stone might have been due to other physical causes, as, for example, to a spring urging it forward, in which case the same piece of scaffolding, a force represented by the same line in the same position, would occupy its place between the cause and the effect ; and

3. Because the effect might have been different, while the physical cause remained the same—thus, if the stone lay on the ground, what the vicinity of the earth would have occasioned is stress between the stone and the ground.

Accordingly by referring effects in Nature to the operation of forces, we are enabled in each case to indicate with accuracy the intensity and direction of the effect, without having to specify (*a*) which of several possible physical causes is the one in operation, or (*b*) which of the possible kinds of effect is that which is being produced : and this in practice is found to be an immense convenience.

Such is an outline of the principles that underlie the dynamical investigation of Nature, which is the form of investigation that penetrates most deeply into its secrets. The dynamical investigation of nature being the most complete from the physicist's standpoint, is, of course, to be preferred to any other wherever it can be employed. Our present knowledge of astronomy, of rigid dynamics, of elasticity, of hydrodynamics, are among its great achievements But there are other sciences, in which we cannot penetrate so close to the origin of things, but which are, nevertheless, amenable to mathematical treatment onwards from a station less deep-seated. In these we begin with happily chosen equations, the truth of which we have not succeeded in tracing to their dynamical source in Nature, but the consequences of which we can calculate and compare with what we observe to occur. Of this kind are the exquisite theory of light which was developed by M'Cullagh, and the enormous strides which our knowledge of electricity has made within the last half century, culminating in the marvellous electromagnetic theory of light.

In all such sciences we are greatly helped by mechanical illustrations, which may be regarded as working models, that, though they

* Abstract from an article on "The Kinetic Theory of Gases, regarded as Illustrating Nature," in the *Phil. Mag.*, October, 1895.

* The author has endeavoured to trace out what it is that really occurs in all such cases. See his Paper "On the Relation between Natural Science and Ontology," in the *Scientific Proceedings* of the Royal Dublin Society, Vol. VI. (1890), p. 475.

† This course is much to be preferred, because it effectually avoids the risk of throwing dust in our own eyes. The justification of the Physical Hypothesis is its utility, not its truth—its incomparable efficiency as a means of investigating Nature ; and it is better, though not essential, that students of Physics should make no mistake about a matter of this kind.

Digitized by Google

do not in the least profess to represent the unknown dynamical condition which exists in Nature, furnish us with an apparatus which operates in ways that we can both compute and conceive, and which produces results that, in some important respects and within ascertainable limits, follow laws the same as or analogous to those that prevail in the part of Nature which is illustrated by them. Of this kind is that most useful and simplest wave-theory of light which represents it by an undulation of mere transverse vibrations. Of the same kind are the various attempts to represent the "texture," which must prevail in the luminiferous ether. And somewhat akin to these are those instructive analogies which can be traced out between different sciences, wherever in both the same differential equation governs the progress of events. Thus, when a current of electricity is turned on to a circuit, the current penetrates the wire from its surface towards its core, by the same law as that by which heat would, by conduction, be carried inwards from the surrounding dielectric—a process already familiar to us, and which, therefore, makes the sequence of events in the other case easily conceived.

Again it must be remembered that in every dynamical investigation, what the mathematician really investigates is not the problem presented by Nature, but some simplification of it. The legitimacy of this process and its value depend upon the important circumstance that, in dynamics, a slight change in the data leads only, at least for a time, to a slight change in the result. Thus in computing the mutual perturbations of the planets, the planets may be treated as though they were spheres, made up of untextured spherical shells each of a uniform density throughout; and it may be left out of account that they approach to being spheroids, with mountains on their surface, irregularities of a like kind at greater depths, rocks in those mountains, minerals in those rocks, a different molecular texture in each mineral, tidal strains, heat expansions by day, contractions by night, and so on, with numberless other details. Now it is legitimate to omit all these from our calculation, for though every one of them produces its effect in actual Nature, the difference between the outcome of their joint operation and that computed from the greatly simplified data of the mathematician is too small to make any approach to being perceived by any human agency. Hence, for any purpose which is of use to man, the approximation arrived at by the simpler problem is sufficient, wherever the errors are of such a nature that they are not cumulative. Nevertheless, it should be clearly recognised that it is a mechanism illustrating Nature, and not Nature itself, that has been mathematically investigated. So it is with all dynamical investigations: the data of Nature have to be simplified to bring the task within the range of man's power over mathematical analysis; and the result is satisfactory because of the important fundamental principle referred to above, that in dynamics a slight modification of the data furnished by Nature may be safely made, because it leads only to there being a small difference between the calculated result and that which occurs in Nature—of course, care being taken in each case that the approximation of the computed result to what occurs in Nature shall be sufficiently close for the object we have in view.

CABLE-MEASURING WHEEL.

The accompanying illustration represents an apparatus made by Messrs. Johnson and Phillips, intended for measuring lengths of cable. The wheel is usually made two yards in circumference, and the one shown is suitable for measuring either small wires or cables up to 1in. in diameter. The wheel being placed *outside* the framework, the cable can be removed without trouble, either during or on completion of operation. The counting gear is placed *inside* the framework to minimise risk of damage. The counter is fitted as usual with bell to indicate any arranged length. The jockey wheel is of large diameter to give greater gripping surface and to prevent slip. The pressure exerted by it, instead of being adjusted by loose weights, is varied by simply sliding the balance weight up or down the lever on which it is mounted. Adjustable guide wheels are provided on each side to make a large cable take a larger proportion of the circumference of the wheel, and so secure freedom from slip. The counter registers absolute revolutions, the figures on the counter altering their position exactly at the end of each revolution. This the makers find much better than the worm and worm-wheel arrangement, in which, after a little wear, the measuring wheel is liable to make half a revolution without moving the finger on the counter.

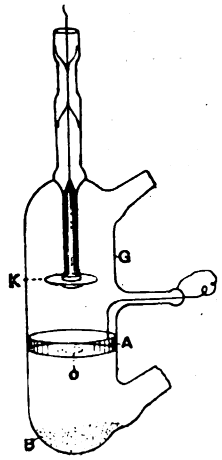
NOTE ON THE EFFECT OF THE GLOW-DISCHARGE ON OXIDE OF LEAD.*

BY E. WARBURG.

1. Oxide of lead absorbs large quantities of gas from the atmosphere and liberates them slowly in a partial vacuum. On heating the oxide these gases are also liberated; heated in the atmosphere and immediately brought into a good vacuum, no appreciable quantity of gas is evolved.

2. Yellow oxide of lead recently heated to a dull red was placed in a glass tube of 20mm. diameter, and was evenly distributed along the tube, which was then filled with oxygen at a pressure of 2·5mm. of mercury. A glow-discharge from a storage battery of 600 cells was then passed between aluminium plates or wires. Very soon the substance near the luminous portions of the discharge, alike at the cathode and anode, became chocolate brown, while the dark parts did not change colour. Rise of temperature of about 100deg. helped to produce the effect, but did not do so by itself. From this it seemed to follow that the oxide of lead, under the influence of the discharge, absorbed oxygen, and was thereby partly transformed into peroxide of lead. Further experiments proved that the phenomenon was accompanied by a reduction in the pressure of the gas, which could be still further reduced by shaking the tube, and thus bringing the unaffected parts of the oxide to the surface (*see* § 5). On the advice of Prof. Elbs a mixture of dilute hydric chloride, potassium iodide solution, and powdered chloride of zinc was made and divided into two equal portions. A piece of the unchanged oxide of lead was now brought into contact with one portion of the mixture, which became at once light blue;



into the other portion was put a piece of lead oxide that had been subjected to the discharge, and this gave the mixture a very dark blue colour. The latter oxide, therefore, contains peroxide of lead.

3. The experimental tube having recently heated oxide of lead evenly distributed in it, was filled with hydrogen at a pressure of $\frac{3}{10}$mm. of mercury. Under the effect of the glow-discharge the substance became intensely black, but again only near the luminous portions; but after a time the oxide near the dark portions were affected. It seems, therefore, that oxide of lead in contact with hydrogen is partly reduced by the glow-discharge.

4. When the experimental tube was filled with rarefied nitrogen there was no visible change of the oxide of lead after the discharge.

5. The question is whether the reactions described in paragraphs 2 and 3 are a direct consequence of chemical transformation produced by the current in the gases, or whether they merely originate from the light or the radiation of the glow-discharge. Several things point to the latter alternative. Firstly, the effect appears to come from the luminous portions of the glow-discharge. Secondly, the effect appears to be confined to the surface of the oxide of lead, as parts directly under the surface show no change of colour. If a tube of larger diameter, 45mm., is used, and the glow-discharge is arranged so that its path is a certain distance from the substance, the effect was found to be the same. If, on the other hand, a continuous current of gas is passed through the discharge tube by means of a Kahlbaum pump, and the gas on leaving this is led straightway to a tube containing oxide of lead, no trace of a change can be discovered. Finally, it can be proved that the cathode rays alone produce the effect.

In the glass tube G (*see* figure) an aluminium disc A is placed, which serves as anode, and has at O a circular opening. Through this come the rays from the cathode K, which consists of an aluminium washer covered on the back with mica, and impinges on the bottom of the tube, which is filled with the oxide of lead, B. Wherever the rays struck the substance the phenomenon occurred with hydrogen as well as with oxygen. The experiment succeeded equally with the current of the accumulator battery and with the induced current from a Ruhmkorff coil; in the first case, however, only with a low gas pressure, as it was only with such that the cathode rays could reach the substance. That rise of temperature plays a substantial part in the influence of the positive portion of the glow-discharge is improbable on account of the low temperature of this portion (paragraphs 2 and 3).

6. Some of the substance was put into a glass tube, one end of which was made tight, and on the other closed by a quartz plate 5mm. thick. After the tube was filled with hydrogen at 33mm. pressure, the rays of an arc lamp were passed through the quartz plate by means of a quartz lens right on to the substance, and after 6min. no trace of change was observed. The effects described in paragraphs 2 and 3 depend, therefore, on rays of very small wave length, since quartz is transparent to ultra-violet rays down to wave-lengths of 0·19μ.* When, however, following G. Salet,† two tinfoil rings were placed at a certain distance in front of one another, and connected with the poles of an induction coil, the phenomenon made its appearance at once.

7. There seem, therefore, to be various reasons for thinking that the rays do not effect the gas, but the oxide of lead, and cause a change in *it*, which makes it susceptible to combination with the oxygen and hydrogen. Upon this supposition it seemed probable that when the glow-discharge operated on the substance in rarefied nitrogen, and hydrogen or oxygen was quickly introduced, an effect would be produced. Experiments were made, but with negative results. Experiments with other metallic oxides have led to no results worth mentioning.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

WEDNESDAY, October 23rd.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting at the Royal United Service Institution, Whitehall. Paper to be read: "The Electric Lighting of Edinburgh," by Henry R. J. Burstall.

THURSDAY, October 24th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting. Papers to be read: "Report on the Lille Experiments upon the Efficiency of Ropes and Belts for the Transmission of Power," translated by Prof. D. S. Capper. "Observations on the Lille Experiments upon the Efficiency of Ropes and Belts for the Transmission of Power," by Prof. D. S. Capper.

FRIDAY, October 25th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: "The Radial Cursor," by F. W. Lanckester. "The Development of Arbitrary Functions," by Prof. Perry and Mr. Hunt.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Thermodynamics.—The following is a syllabus of the special course of four lectures on the "Principles of Thermodynamics, and their Application in Engineering," which will be delivered by Prof. Perry, at Finsbury Technical College, on alternate Thursday evenings, from 7:30 to 9 o'clock, commencing on Thursday, October 24th:—(1) October 24th, "How we Calculate exactly the Heat and Work Changes when any changes of volume pressure or temperature occur in stuff subjected only to Fluid Pressure;" (2) November 7th, "The First and Second Laws of Thermodynamics;" (3) November 21st, "Application to Air Engines and especially to Gas Engines; also to Compressors, Exhausters and Refrigerators;" (4) December 5th, "Application to the Steam Engine." One or more additional lectures may be necessary, and if so, their dates will be announced later.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny. Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

HORSELESS CARRIAGES.

It is commonly reported that an eminent lawyer once boasted that he could drive a coach-and-four through any Act of Parliament. The statement did not show much respect for the law itself, nor was it complimentary to the framers of the Acts. Perhaps the gentleman was a Parliamentary whip. We wonder if he would have undertaken to drive the coach without the four horses, which a good many individuals in the present day are wanting to do. The letters and disquisitions that have appeared in the daily papers, trying to find an "open sesame," seem to us somewhat beside the mark. Instead of seeking how far it is possible, in contravention of existing laws, or by misapplied interpretation, to escape from what is generally recognised as the full meaning and intent of the Acts, would it not be better to recognise that the law as it stands plainly and practically prohibits the use of horseless carriages, and instead of cudgelling our brains to find out how we may excuse ourselves for breaking a recognised law, set to work diligently to have the law amended? Is there any good in asking *why* we can do nothing in England without a precedent? Would it not be better to accept as axiomatic the curious fact that, no matter what may originate in the English mind for the public benefit, or to further enterprise, it will, if it involves any deviation from well-known and hard-trodden paths, assuredly have every possible hindrance put in its path until it has been recognised and adopted abroad. The latest instance of this is of special interest at the present time. Now that our good friends the French have demonstrated the feasibility of travelling safely on the public roads in horseless carriages, there is some talk of permitting the pent-up engineering ability of our own land to exercise itself. And having progressed so far, it is to be hoped the infant industry will not be stifled beneath the heavy weight of unworkable Board of Trade or other departmental rules. A slack rein should be permitted, at any rate for a time, and until experience has supplied the powers that be with a little practical knowledge of the thing to be controlled.

The display at Tunbridge Wells on Tuesday, in which Sir DAVID SALOMONS figured so prominently, will, no doubt, give an impetus to the movement in favour of horseless carriages. The most encouraging sign was the crowd of eager and expectant spectators who manifested an intelligent interest

Digitized by Google

in the object of the exhibition, and it is to be regretted that there was not more to be seen. Considering the large number of competitors who took part in the Paris-Bordeaux race, and the many manufacturers in France who are turning out successful "*voitures automobiles*" it is a pity that only those with the Daimler motors were forthcoming, with the exception of the one with the steam bogie in front, exhibited apparently as a sample of what should not be done. This latter device certainly worked well, beating the others as to speed, and had this very desirable quality, that it did not shake and tremble when standing, as did the others. But the smoke when firing up before starting, and the trail of steam behind when running, the undulations of the carriage when passing over the fairly level meadow, and the general appearance, make its chance of adoption in this country very remote.

A very interesting exhibit was a petroleum driven tricycle, ingenious in conception and with all the parts constructed and arranged with the neatness and finish characteristic of French work. The rider was at a disadvantage; running on a meadow is obviously harder work than on a good road, and the field was, moreover, on the slope, so that the pedals had to be used more than would probably be necessary in ordinary practice.

Where were the electric carriages? It cannot be said that there are none, because, as is well known, they have threaded their way through the streets of London years ago, and are presumably in working order to-day. Why, also, did not some of the English makers of petroleum carriages put in an appearance—Mr. J. H. Knight, for instance, who has been running about Farnham up hill and down dale for months in his little carriage? Why, again, the exhibition being for horseless carriages, was the Daimler motor fire pump introduced? It certainly did good service in clearing the arena of the too eager promiscuous public, who, contrary to police protest, crowded in and blocked the view. Perhaps it was a precautionary measure, because, as is too well known, the light oil used is risky, and if it took to firing in the wrong place would make short work of the carriages.

The most interesting episode occurred after the exhibition was over. As the large concourse of people were wending their way back to Tunbridge Wells, some on foot and some in carriages, the "*voitures automobiles*" came careering along, overtaking the other vehicles and threading in and out amongst them with apparent ease. To the credit of the Tunbridge Wells horses, be it said, they shied neither at the Daimler cars nor even at the steam bogie. If the horseless carriage movement is to be anything of a success the Tunbridge Wells exhibition will have to be followed by many another, and a greater variety of exhibits must be aimed at.

REVIEWS.

Electrical Laboratory Notes and Forms (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. (London: "The Electrician" Printing and Publishing Company, Limited. 1895.)

In a system of laboratory instruction, which aims at training a large number of students to make exact quantitative measurements, the demonstrator is required to give close attention to every student. Now, in order to save the teacher's time and energy in repeating practically the same directions to different students, and in insisting on careful and systematic records being made of the observations taken, some of the instructions for each experiment are usually given in printed Papers. The teacher may add verbal explanations as far as necessary. Such printed Papers have been in common use in our technical colleges during at least the last 13 or 14 years. In some cases the notes of physical laboratory work have been arranged in book form, each book being suitable for a year's course of instruction.

The volume before us contains a collection or selection of Electrical Laboratory Notes and Forms intended for the use of students and the assistance of demonstrators who are engaged in the work of systematic laboratory teaching. Twenty elementary and twenty advanced experiments, all of important bearing in practical work, are taken up, and some of them are dealt with in a complete and thorough manner. At the outset the reader is reminded that one object of laboratory teaching is not merely to carry out a particular set of experiments, but to train the student in habits of accuracy of observation, and in proper methods of recording results. Instructions are given for the use of these Notes and Forms. The student is rightly recommended to make a careful diagrammatic sketch of the arrangement of the apparatus and circuits for each experiment, although it is not clear on which part of the sheet the sketch is to be made, if there at all. The first two or three pages of each Paper are occupied with an account of the experiment and measurements, and with Notes on the precautions necessary to be observed in carrying it out properly. The student may obey orders as here given; he may make careful observations and record the results neatly in the Forms, and yet fail to realise a very important part of laboratory instruction. It may hardly ever occur to him to think of the degree of accuracy to which a measurement is made, or of the limits of possible errors in his work. If unable to do this exactly, the student should, at any rate, be trained to think for himself, to criticise the experiments, measurements and results, paying special attention to any source of error which may not be allowed for or corrected, and to show clearly how each error referred to would affect the final result. In this way the student would be led to make *deductions* that strike him as being borne out by the experiment in hand. In the Notes Dr. Fleming does not direct the student to discuss his results and draw conclusions.

A great deal must depend upon the demonstrator as well as on the apparatus available, and all students cannot be taken as of exactly the same mental calibre and proficiency according to rigid cast-iron forms. There should be room left for variation, and slight difficulties will only tend to stimulate thought, and raise the student above the automatic machine, by making him self-reliant, and calling forth some originality in carrying out experimental investigations.

A special feature of the volume is that for every experiment two or three blank pages or Forms are appended, ruled into columns with headings setting forth the quantities to be recorded. These are supposed to take the place of the time-honoured note-book, which is thus dispensed with altogether! The practical value of these blank tabular sheets, for educational purposes, may be questioned. If the headings only were given, the student would be more likely to profit by the exercise of copying them into his note-book, and ruling columns for himself. Practical experience as a demonstrator in an electrical laboratory soon leads one to recommend the average student, at any rate the beginner, to use a rough note-book in which to take down the results of the experiments, with sketches or diagrams made in the laboratory, and to enter these neatly in another book at home. The ruled pages might be used for the latter purpose, instead of for the rough notes, as indicated. Again, we find no directions given as to how the record is to be kept on those sheets which have not columns for all the quantities observed. To be reliable and useful the table must include not only the results of calculations made from observations, but also the *actual* figures observed. Attention to this point frequently enables the student to detect errors and check his calculations afterwards.

Dr. Fleming recommends the student, where possible, to calculate the results and plot out curves *at the time* of making the observations, during the progress of the experiment. The expediency of this plan is questionable for the ordinary student in the laboratory, although often useful for the trained experimenter. Errors may be noticed at the time, it is true, but some

Digitized by Google

students may be tempted to make the readings fit the result aimed at; and besides, the observations are not likely to be so reliable, because the attention is diverted.

In experiment No. 20, a student has to work out at once during the run the indicated horse-power of a gas engine from the cards he takes at regular intervals of ten minutes. This is rather much to expect from an average beginner, especially when the explosions in the engine cylinder are irregular in number and power, and the diagrams vary accordingly. Moreover, no record of the card is given in the table, except the indicated horse-power so found! In this test of a gas engine and dynamo plant the so-called "*combined efficiency*" ignores the quality of the gas used and consequently the amount of heat supplied to the gas engine, so that, as far as the gas engine is concerned, only the *mechanical efficiency* is dealt with; and the volume of gas obtained is of very little value without its composition and heating power, together with the temperature and pressure of supply, yet these are not even mentioned. The measurement of the heat carried off by the cooling water in the cylinder jacket is also inexact. A water meter is supposed to give the *volume* of water passing, and although the inlet and outlet temperatures are to be observed, there are no columns left for them in the table. The *weight* of water is really the quantity required, and it is usually obtained by allowing the water to flow from a calibrated tank or into a vessel placed on a platform weighing machine. The exhaust gases from the cylinder escape without any notice whatever. The instructions for this "complete" test of a gas engine and dynamo plant are clearly incomplete.

Several of the Notes need careful correction and revision, and it is surprising this has not been done before publication. Two or three examples will suffice to show the sort of thing one finds at a glance. In (No. 18) the brake method of testing "large single motors, which cannot easily be moved from their positions," and of "1 H.P. or more," the student is seriously directed to use a "flywheel" only "10in. or 12in. in diameter, and 1in. or 2in." broad on the rim, with "two ropes ½in. diameter, laid parallel to each other along the edge of the flywheel and kept from slipping off by three little cleats"! We are then told that the weight attached to the rope stretches it. The explanation is confusing. Columns are wanting for the electric power put into the motor, and for the power given out on the flywheel—their ratio only is noted. In No. 29, the term "mean-square value" is misleading, and should be "square root of mean square," which is written in symbols $\sqrt{\text{mean}^2}$.

No. 30 (page 2): the expression "one of Lord Kelvin's multicellular electrostatic voltmeters has its terminals *short-circuited* by a *well-insulated* condenser" is hardly permissible. (Italics are ours.) The long explanation, at the foot of page 2 and top of page 3, regarding the capacity current of a voltmeter, is not to the point. The voltmeter is connected to the terminals of a condenser, which is kept charged by a succession of contacts; after the first few rushes of current, when the condenser has become fully charged, the subsequent passage of current into the condenser will merely be that required to make up for leakage; and this will be negligibly small compared with the "capacity current" when the condenser is kept constantly connected to two points, between which there is an *alternating* potential difference. The explanation given would thus appear to be entirely beside the mark. Probably the author had in his mind the determination of the ratio of the two resistances by the ratio of the readings of an electrostatic voltmeter when connected across a fraction of the resistance, and the whole of it respectively.

No. 35. In dealing with the efficiency test of a secondary battery, the author fails to impress upon the unwary student the important fact that the single set of readings which he is directed to take is utterly useless so far as a determination of battery efficiency is concerned. The importance of repeatedly charging and discharging the battery until the process becomes strictly cyclical is not even alluded to.

Still, many of the advanced Notes are very elaborate and complete, and will be found useful in well-appointed electrical laboratories, when not followed too closely, and supplemented by the instruction of a demonstrator. WILLIAM ROBINSON.

THE BRISTOL-KINGSWOOD LINE.

It is not as frequently as we would wish, that we have the opportunity of inspecting, in this country, such solid and thorough electrical engineering as that which we had the pleasure of visiting last Monday, when we joined a party formed by the British Thomson-Houston Company, and travelled down to Bristol to see the new electrical system of the Bristol tramways. Constructed as it has been on the Bristol-Kingswood line, the trolley system of electric traction, now first making its appearance under the new Board of Trade regulations, has evidently come to stay; and we may therefore reasonably look forward to a recrudescence of electrical manufacturing activity. Things have settled down into a steady state, in electric lighting matters; and though contractors may still expect many an electric lighting job, it is to the extension of electric traction and motive power that they must turn for their principal sources of revenue in the near future. We shall be late in the field, without doubt, when we compare our progress with that in America and on the Continent. But better late than never; and we gain by our tardiness, in being able to reap the benefit of foreign improvements, and to profit by the warnings which their earlier mistakes afford. Speaking of tardiness, it is not a little surprising that, of all the cities of the realm, Bristol, which for decades has enjoyed the well-earned epithet of "slow coach," has at last awoke and scored first in the introduction of tramway traction under the new and we hope relatively permanent *régime* of the Board of Trade. It is true that there already exist two other English tramways—that at Leeds and that in South Staffordshire—where the overhead trolley system has for some time been in vogue. But, apart from the tentative and experimental nature of these lines, they belong to the age which preceded the laws upon which all such lines will in future have to be built.

The section of the Bristol tramways system which has been selected as the first portion to be converted from horse traction to electric traction is about four miles in length. It extends from Old Market-street, the Mile End-road of Bristol, eastward through a densely populated district to the suburb of Kingswood. The route is very varied in its features; sometimes passing through broad thoroughfares which allow of a double track, and double-bracketed trolley poles between the tracks; sometimes extending through narrow streets, where single track or interlaced tracks are rendered necessary, and where the poles must be placed on the kerb, and must have very long single brackets to support the two trolley wires. Nowhere, however, is there any very sharp curve; but the gradients are particularly trying on the forward and the return journeys, though more particularly on the former, a succession of stiff grades having to be surmounted. The steepest incline is about 1 in 15, and extends along some 220 yards of track. We happened to be on a car that, in the course of its inaugural progress, had to re-start on this particular gradient; and it may be worth mentioning that the motors took the severe load very well, and rapidly gained speed up the hill.

Each of the motor cars is equipped with two Thomson-Houston motors, geared to the car axles by single reduction spur gear. The enclosure of this gear in an oil box will tend to minimise friction and wear. The motors are started on the series-parallel system; and the regulating resistance is not required to be kept permanently in the circuit unless the speed is to be very low. The electrical equipment of the motor cars also includes a number of glow lamps, for head lights and inside lighting. Some of these lamps are connected in series directly to the trolley; but the remainder derive power from a small storage battery carried on each car, and are thus alight when the trolley has to be detached from the overhead conductor. Some of the trailers are also fitted with both oil and electric lamps, the latter for use when they are trailing, and the former when they are drawn by horses.

There are at present 12 motor cars. The whole of the electric power for these is supplied from a power house erected on the site of the old tram-horse stables, about midway between the two termini of the electric line. The

Digitized by Google

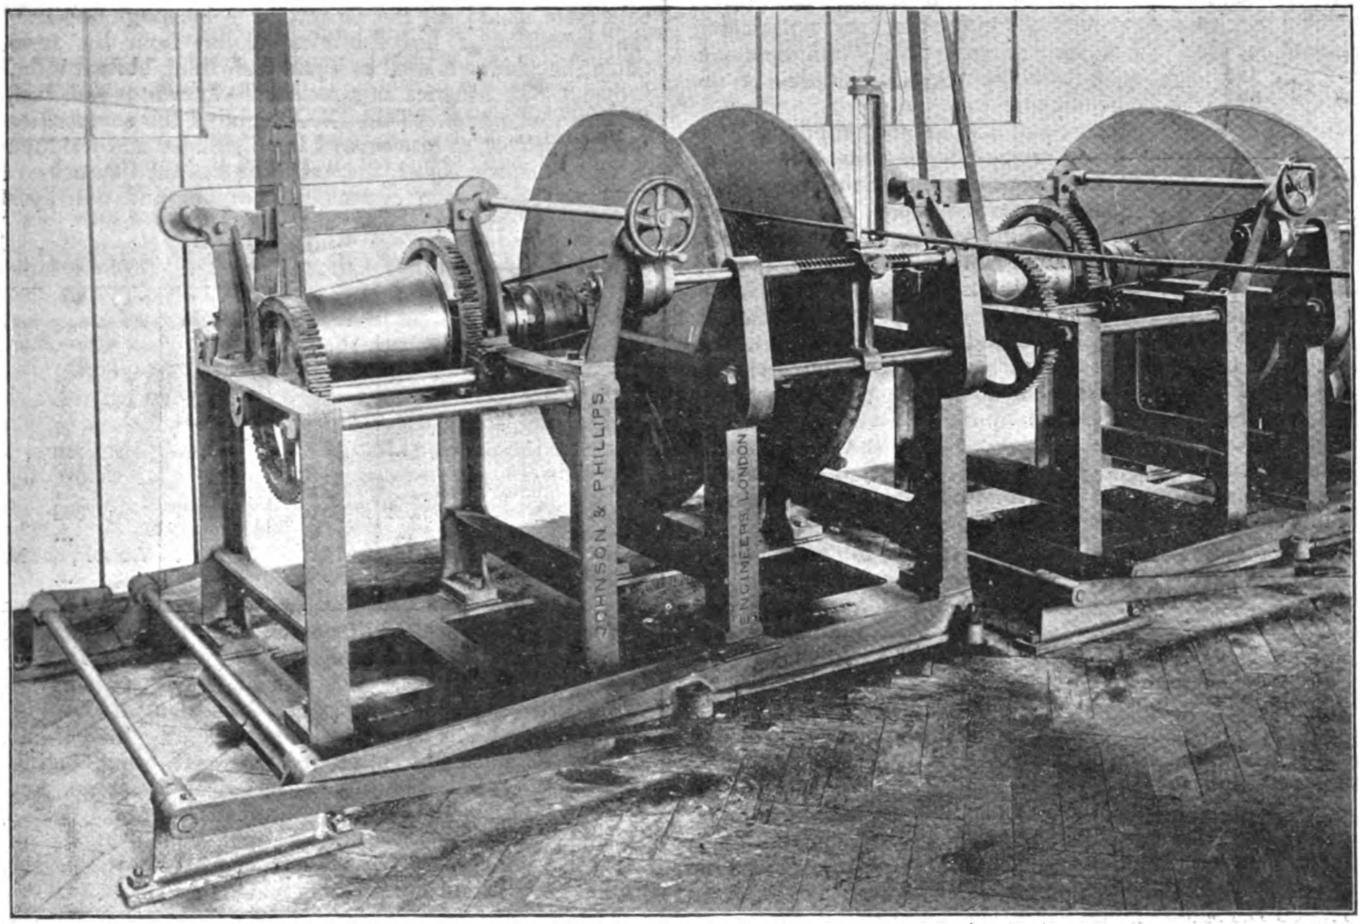
boiler and engine rooms are annexed to the commodious and well-arranged car sheds; the batch of substantial buildings also including repairing shops and other useful accessories. Within the boiler house there are, at present, two Lancashire boilers, fitted with mechanical stokers and other economising appliances. Steam at about 140lb. pressure is supplied from these to three sets of generating plant. Each of these sets comprises a 135 H.P. compound, two-crank Willans engine, running at 380 revolutions per minute, *rope-geared* to a Thomson-Houston four-pole continuous-current generator, capable of developing 200 amperes at 550 volts, at a speed of 650 revolutions per minute. The rope coupling of a Willans engine for electric power generation was in itself a novel, if not an unique, sight. It has been aptly said that in England we make our engines to suit the dynamo; in Germany they reverse the process, and make huge dynamos to suit their huge slow-speed marine-type engines; whilst in America they make a fit as best they can. It is evidently a piece of American practice that we have here, for we cannot imagine that anyone concerned thought high-speed engines coupled to their dynamos by cotton ropes were in themselves a desirable or up-to-date arrangement.

An interesting matter connected with the construction of this line leaked out during the characteristically brilliant speech with which Prof. Silvanus Thompson delighted us at the luncheon. We mention the incident because it furnishes an illustration of the care and technical skill with which the gas and water companies intend to watch the progress of electric traction in the vicinity of their works. It appears that the Bristol gas and water companies have long engaged Prof. Thompson's professional eye to scrutinise the construction of the line. No doubt the confession of this *incognito* shadowing came somewhat as a surprise for the contractors; but, doubtless, too, they breathed more freely when the learned professor declared that he would be very astonished indeed if, for many years to come, any electrolytic troubles should arise on the Bristol-Kingswood electric tramway.

The successful opening of this line of electric tramways is now an established fact. We hope that its successful continuous running will prove equally a fact, whether as an engineering work or as a commercial undertaking. Everything about the opening ceremony went off with great *éclat*, thanks to the combined generosity of the tramway company and the contractors, the British Thomson-Houston Company. Indeed, the only possible occasion for criticism is the magnitude of the ratio, when we put "the ceremony" in a numerator and "four miles of tramway" in the denominator. We have, of course, no wish to curtail our own enjoyments; but, for the sake of the industry, we shall be better pleased when the inauguration of a mere four miles of electric tramway in this country will be such a common and everyday occurrence that the event will call for little or no flourishing of trumpets, nor require that any portion of the electrical Press should indulge in the chanting of laudatory Latin songs.

AUTOMATIC COILING APPARATUS.

Our illustration shows some winding machines, of which three sets have recently been supplied by Messrs. Johnson and Phillips to the Postal Telegraph factory. The machines are designed for winding the cables on to collapsing drums for the purpose of making the cables into coils. They are fitted with automatic traversing gear for flaking the cable accurately on the drum, the speed and length of traverse of this gear being capable of variation to suit different diameter of cables. As the cable is being wound on to the drums an attendant stands by and examines it, to see that the outer covering is perfect, and it is therefore necessary that the speed of the cable shall be fairly constant. With a constant speed of the drum the speed of the cable would, of course, increase as the drum fills; this is compensated by means of the cone driving pulleys along



General View of Wire Coiling Machine.

Digitized by Google

which the belt can be shifted by means of a small hand wheel. The machines are driven from a similar cone on an overhead countershaft, through a friction clutch, which is actuated by means of the foot levers and connecting rods shown.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

Gas and Oil Engines.

Gaseous and Liquid Fuel.

Classification.—The general properties of fuel and the principles of its combustion have already been stated. Gaseous and liquid fuels possess the same general properties and liberate heat, by combustion, in the same way as solid fuels. There is, however, this difference between the two cases, that solid fuels are invariably burned outside the engine, while gaseous and liquid fuels are capable of both internal and external combustion. The sources of gaseous and liquid fuels are very varied; they may be divided into (1) natural and (2) artificial sources.

The following Table includes the principal fuels in each class:—

Table XXVII.—*Gaseous and Liquid Fuels.*

	Natural.	Artificial.
Gaseous.	Natural gas.	Coal gas.
	Marsh gas.	Acetylene.

Coal Gas.—The two most important fuels in the above Table are coal gas and petroleum, so far as this country is concerned; but in those countries where light hydrocarbon gases are freely emitted from fissures of borings in the ground, as in the oil districts of America and Southern Russia, natural gas is of considerable importance as a fuel. Coal gas is a manufactured article of varying composition and quality. It is a mixture of certain hydrocarbons with carbon monoxide and certain useless gases. Into its mode of making we need not here enter; the electrical engineer is chiefly concerned with it as a fuel supplied through pipes. Its average composition may be taken as that of the gas used in the Society of Arts trials of gas engines, an analysis of which is shown in the following Table:—

Table XXVIII.—*Average Composition of Coal Gas.*

Constituents.	Percentage volume.
Heavy hydrocarbons	3·77
Marsh gas (CH_4)	37·34
Hydrogen (H)	50·44
Carbon monoxide (CO)	3·96
Carbon dioxide (CO_2)	0·51
Oxygen (O)	0·00
Nitrogen (N)	3·98

From the large percentages of free hydrogen and lighter hydrocarbons, coal gas becomes an exceedingly rich fuel. The average thermal value per pound weight may be taken at 22,000 B.T.U.—a figure which is often exceeded, though also sometimes far from being reached. This datum is equivalent to a thermal value of 740 B.T.U. per cubic foot of gas; the specific volume being about 30 cubic ft. per pound. The evaporative power of average coal gas is, therefore, about 19·5lb. of water from and at 212°F. per pound of gas. Using bituminous gas coal, about 4·5 cubic ft. of commercial gas can be produced from one pound of coal, apart from any water gas which may be made with the coke residue. Gas works are now extensively fitted with coke-consuming gas plant, the products of which are added to the actual volatilised coal gas.

Petroleum.—Crude petroleum is a mixture of several liquid hydrocarbons of the paraffin (C_nH_{2n+2}) series, traces of the olefines also being present in the petroleum of certain districts. Its principal occurrences are in Southern Russia, on the shores of the Caspian Sea, and in North America, but considerable quantities of crude petroleum have been obtained in many other parts of the world. The natural oil has, unfortunately, never been obtained in commercial quantities in the United Kingdom. The occurrence of the oil in the vicinity of salt deposits has given rise to the hypothesis of their similar origin, yet the origin of petroleum is still enshrouded in mystery. In America the oil is pumped from great depths after boring operations have been undertaken, but in the Caucasus it often spouts copiously through the bore-holes. For example, when the Droojba well was uncapped a column of oil, some 18in. in diameter, rose to a height of 300ft., throwing up and wasting nearly 500,000 tons of oil before it could be checked.* In the Caucasus not more than 10 sq. miles of oil district have been exploited, while some 1,800 sq. miles have been proved to be rich in oil. In America the prospects of continuous supply are nearly, if not quite, as hopeful.

Crude petroleum is unsuited for commercial use, partly because of the presence of explosive hydrocarbons and partly on account of earthy impurities. It is subjected to processes of settling and distillation before being exported for use. The distillation is fractional—*i.e.*, it is carried on at successively higher temperatures, and is in several stages; but there are three principal stages: (1) The separation of low-flashing petroleum spirit; (2) the separation of burning oils; and (3) the separation of heavy lubricating oils from the residue. Often the residue is used as liquid fuel, being burned in boiler furnaces. In America this residue is known as *residuum*, in Caucasus as *astatki*. Table XXIX. shows the composition of Russian petroleum in terms of the distillates and residues, as given by Ludwig Nobel, the "oil king" of the Caucasus. The Table is based upon commercial outputs, and not upon a laboratory analysis:—

Table XXIX.—*Yield of Oils from Russian Crude Petroleum.*

Commercial oils.	Percentage volume.	Specific gravity.	Flashing point in degrees Fahr.
Benzine (light oil)	1·0	0·725	14
Gasoline	3·0	0·775	32
Kerosene (burning oil)	27·0	0·882	77
Soliarovi (lubricating oil)	12·0	0·970	212
Veregenni	10·0	0·890	302
Ordinary lubricating oil	17·0	0·905	347
Cylinder lubricating oil	5·0	0·915	392
Vaseline	1·0	0·725	...
Liquid fuel	14·0	Variable.	Variable, but high.
Lost in refining	10·0	...	...

Very frequently all the residue after kerosene has been distilled is used as liquid fuel, representing about 65 to 70 per cent. of the crude oil. The specific gravity of this refuse varies between 0·889 and 0·911. The yield of burning oil from American oils is, on the average, greater than from the Russian, as much as from 50 to 60 per cent. being obtainable. There are several qualities of American kerosene, known commercially as "Tea Rose," "Royal Daylight," &c. The specific gravity of these varies from 0·802—in the more expensive quality—to 0·820, in the cheaper kind; and the flashing point similarly varies between 100°F. and 122°F.

The heat of combustion of 1lb. of refined petroleum (burning oil) is on the average about 27,000 B.T.U. As high as 28,100 B.T.U. may be obtained from the lighter and more expensive oils; but, on account of their low flashing point, these are not always safe. Much lower value will be obtained from the cheaper and very crude oils; but these may leave a

* "The Region of the Eternal Fire."—Marvin.

Digitized by Google

thick residue after combustion, which renders them unsuited to most oil engines, and unsatisfactory in any case. Russolene, or Russian kerosene, "Tea Rose" and "Royal Daylight" are the brands most commonly used in oil engines.

Natural Gas.—The outflow of oil from a newly-drilled well is generally preceded by the discharge, under enormous pressures, of gaseous hydrocarbons. In many places the gas soon subsides, and oil follows; but in other places a steady flow of gas is maintained, and the discharge may be drawn off through pipe lines, for lighting purposes or for combustion under a boiler. In America natural gas is largely used for steam raising; and the practical thermal value of the fuel is estimated as being equal to about 30,000 cubic ft. of the gas per ton of coal. According to this estimate, the thermal value is about 28,000 B.T.U. per pound of the gas. Richer yields of the gas often exceed a thermal value of 30,000 B.T.U.

Water Gas.—Pure water gas is obtained by the action of steam on incandescent carbon. It is rarely if ever used commercially; but the action is the basis of several commercial fuel gases, notably of Dowson gas. The action which takes place is endothermic, and it is represented by the following chemical equation—

$$H_2O + C = CO + H_2 . . . . . (97)$$

A mixture of hydrogen and carbon monoxide gases results. According to the equation, the mixed gas contains 93·33 per cent., by weight, of carbon monoxide and 6·66 per cent., by weight, of hydrogen. One pound of carbon will develop 2·5lb. of the gas. The calculated thermal value of the gas is 6,100 B.T.U. *per pound of the gas*, or 15,250 B.T.U. *per pound of solid carbon* contained in it. Now, the total heat of complete combustion of one pound of solid carbon is 14,500 B.T.U. Hence, the process is partially one of storage of energy; for the total heat of the gas is greater than that of the solid carbon, the surplus heat being supplied by the furnace which keeps the carbon incandescent and raises the steam.

Gas Producers and Storage Plant.

The Dowson Gas Plant.—Although the practical introduction of generator gas-fuel is to be attributed to Sir William Siemens, it will probably be acknowledged by all that the chief impetus which has been given to the use of gaseous fuel generated from fixed solid fuels came from Mr. J. Emerson Dowson, whose literature on the subject has widely extended the knowledge of this form of heat source, and whose admirable generating plant has rendered its use a commercial possibility.

Dowson gas is a form of diluted water gas, made by the action of a steam-and-air blast upon incandescent carbon, usually anthracite, but occasionally coke. The endothermic action indicated by equation (97) takes place; but in addition a portion of the carbon is completely consumed by the air, this latter action serving to maintain the high temperature of the generator. An illustrated description of the Dowson gas generating plant recently appeared in conjunction with an account of the Morecambe gas-engine electric supply station, in *The Electrician*, October 4, 1895, p. 753. On this account we shall here pass the detailed description of this form of gas generator.

Composition of Dowson Gas.—It has already been stated that Dowson gas is not a chemical compound, but a mixture of many gases. In actual practice the proportion of its constituent gases is variable within considerable limits, and the thermal value of the gas suffers corresponding changes. Firstly, the composition of the gas, in practice, seems to depend on the solid fuel used, anthracite giving, in general, a richer gas than coke. It appears that with coke too much air streams through the porous fuel and out at the top of the generator, without generating combustible fuel. Thus the percentages of nitrogen and of free oxygen are apt to be higher than where anthracite is used. Again, the composition of the gas depends upon the pressure of the steam blast, and upon the proportion of air which that blast can inject with itself. When the generator is called upon to develop gas very fast a high pressure of blast will be required, while when the demand for gas is low the pressure will have to be throttled down. Consequently the composition of the gas—and its dynamical power in the engines—will vary with the load put upon the gas generators. A test flame is usually kept burning near the generators, and the height and colour of this flame serve as some guide to the quality of the gas being produced. Table XXX. gives the average of several analyses made by Dr. Monaco on the gas given off directly from the generators, in a station at Canale, Piedmont. According to this average result the heat of combustion of one pound weight of Dowson gas is about 2,600 B.T.U., and the heat of combustion of 1,000 cubic ft. is 177,500 B.T.U. The theoretical volume of air required for this combustion is equal to the volume of the gas burned.

Table XXX.—*Average Composition of Samples of Dowson Gas taken from a Gas Generator at Canale, Piedmont. Temp. 32°Fah. Pressure 14·22lb. per sq. in. (abs.).*

——	Percentage volume.	Percentage weight.	Weight in pounds per 1,000 cubic ft. of Dowson gas.
Carbon dioxide (CO_2)...	8·40	14·73	10·057
Oxygen (O)	0·90	1·15	0·784
Hydrogen (H)	16·47	1·32	0·897
Carbon monoxide (CO).	27·50	30·67	20·946
Nitrogen (N)	46·73	52·13	35·595
Total..................	100·00	100·00	68·281

Thwaite's System.—For the production of Dowson gas, fuel composed entirely of *fixed* carbon (neglecting mineral matter) is requisite, and practically anthracite is the only fuel that answers the purpose. In many parts of this country the relative costs of anthracite and small bituminous coals are such that it is cheaper to use the latter in steam plant than the former in gas plant. Yet these parts are the most populous and industrial in the country. The need, therefore, has arisen for a gas generator which will generate fixed gaseous fuel from bituminous coal, using both the volatile and the fixed constituents of the coal. Such a gas plant has been devised by Mr. B. H. Thwaite. The principle of its action consists in the turning of the volatile portions of the fuel into products of complete combustion, and then reconverting them into combustible gas—this time *fixed*, not volatile—by passing them through a furnace of incandescent fixed carbon obtained from the coked fuel. The result is that all the hydrocarbons are turned into free hydrogen and carbon monoxide, while the fixed carbon produces only the latter of these gases. The only objection that can be raised against the theory of this most ingenious process is that it requires the available energy of the hydrocarbons to be considerably let down or reduced by the combination of their carbon with one equivalent of oxygen.

Gas Holders.—Hitherto gas holders have been used, in electric supply stations using generator gas, only as equalisers of the pressure of gas. There has been little or no attempt to store the gas for any great length of time, so as to equalise the load on the generators. At Morecambe, where there are two 75 H.P. Dowson generators and one of 150 H.P., and where gas engines amounting to more than 175 H.P. are daily at work, the gas holder has a capacity of only 1,500 cubic feet. So small is this in comparison to the draught of gas, that with full load on the station and no gas being freshly made the holder will be emptied in ten minutes. At other places the capacity is proportionately low. It is scarcely possible that under these conditions the gas plant can be working at its highest efficiency; and it would be well, in designing such plant, to provide so large a holder as that the fluctuations of load on the gas generators should be reasonably small.

Cost of Generator Gas.—Some facts may now be stated that will assist in making any definite estimate of the cost of working by generator gas. At the Morecambe station the coal is purchased for 18s. per ton, and the cost of fuel per B.T.U. metered out of the station varies from 0·3d. to 0·5d. In addition, the sawdust scrubber is recharged once every three weeks; the coke scrubber once every six months; the boiler consumes about 120lb. of coke per hour; and the

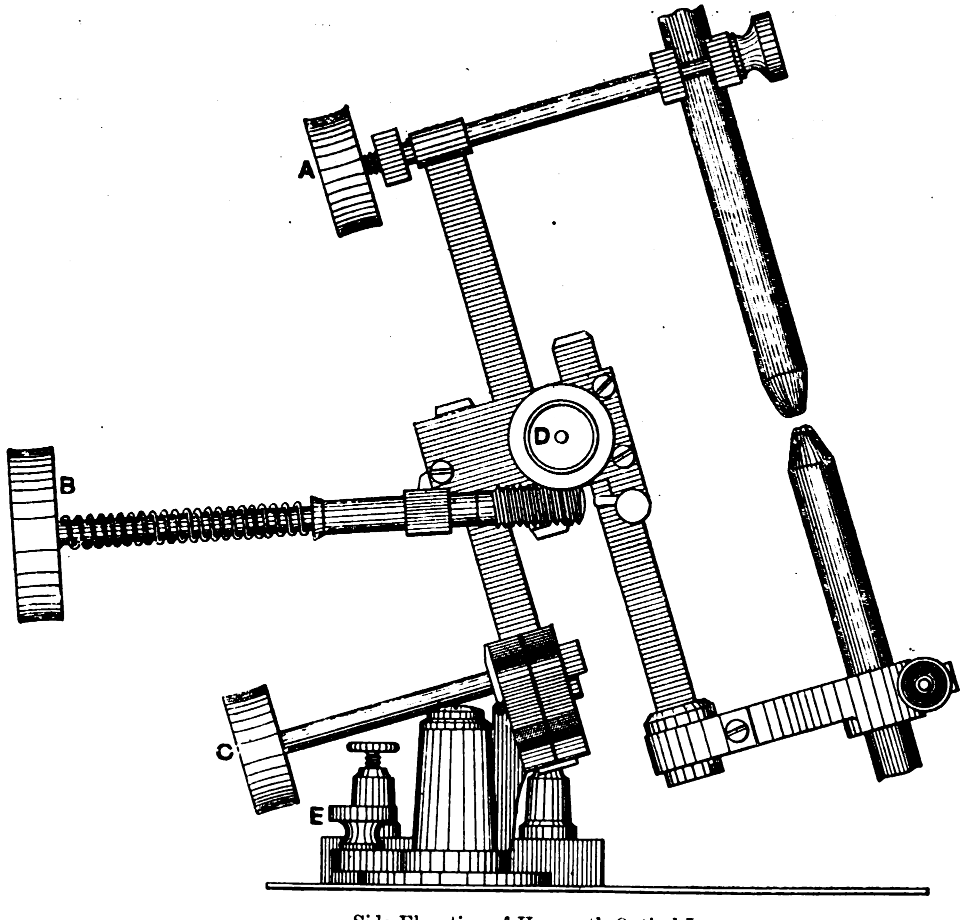
Digitized by Google

attendance required for the whole of the gas generator plant is one man. At the Coatbridge station, where there is a total gas generating capacity of 240 H.P., and where anthracite costs 12s. 6d. per ton, the coal consumed is at the rate of 0·6d. to 0·7d. per Board of Trade unit; the boilers consume 2·5 tons of coke per week; and sawdust for the scrubbers cost 2s. 6d. per week. The output of this station is about 11,600 B.T.U. per quarter in the winter quarter. At a large gas-engine station known to the author, but one not used for public electric supply, two generators each of 100 H.P., one of which is always used as a stand-by only, consume 22cwt. of anthracite per diem, on a 17 hours run, with banking up and stand-by losses included. The electrical output is about 640 units per run. On an average for half a year the coal consumption was 5lb per unit; but in the depth of winter the consumption fell to 4·25lb. per unit.

(To be continued.)

THE ROSS-HEPWORTH PROJECTION LANTERN ARC LAMP.

There has of late been a very noticeable activity among makers of projection lanterns in the direction of introducing the arc light, the general tendency being towards a gear which shall be at least as easy of manipulation as that of the old type of lantern, and resembling it externally as closely as may be. A very complete arc-light apparatus for projection lantern purposes has recently been devised by Mr. Cecil M. Hepworth, and is now being made by Messrs. Ross and Co., of New Bond-street; it was shown in the rough at the *conversazione* at University College this last summer, and attracted deserved attention.



Side Elevation of Hepworth Optical Lamp.

In the accompanying sketch is shown a side elevation of Mr. Hepworth's lamp. The carbon holders are supported by two massive toothed guide-rods, gearing into a pinion between them, which causes them to move in opposite directions. This pinion is connected to the tangent wheel D, which engages with a worm-wheel, and a slow feeding motion is given to the carbons by turning the milled vulcanite head B. Should it be required to bring the carbons momentarily together, the head B may be pushed forwards, causing the worm-wheel for the moment to act as a rack, and imparting a very rapid rotary motion to the tangent-wheel and pinion. A strong spiral spring on the feeding handle causes it to fly back the instant it is released, separating the carbons, and bringing them to the exact relative position they occupied before. Rotation of the top milled head A enables the lanternist to displace the positive cratered carbon relatively to the lower one. Rotation of the bottom milled head C raises or lowers both carbons bodily, so that the crater can be brought into the optical axis. If the milled head B is given a cant upwards, the worm-wheel is disengaged from the tangent-wheel D, and the carbons can be rapidly separated or brought together by turning D. One more movement has to be referred to, and that is a slot and screw E on the base plate, by means of which the entire gear may be swung round as required. The lamp is made to take 13mm. and 10mm. carbons, but, of course, can be arranged to take carbons of other diameters.

Mr. Hepworth's lamp is well made, and seems in every way likely to serve its purpose in a thoroughly satisfactory manner.

The Japan-Formosa Cable.—The manufacture of this cable is now in full swing at the Telegraph Construction and Maintenance Company's Works. Amongst the firms which tendered for this contract must be numbered the two French cable manufacturing companies.

DR. FLEMING'S REPORT TO THE PLYMOUTH ELECTRIC LIGHTING COMMITTEE.

[ABSTRACT.]

After a short glossary of terms, Dr. Fleming states that he was requested to advise: (1) On the electric lighting generally of Plymouth by the Corporation; (2) on the utilisation of town refuse as fuel; (3) on the employment of electric traction in connection with tramcars in Plymouth; and proceeds to preface his remarks by a short statement of the present state of electric lighting in the United Kingdom. These preliminary remarks conclude as follows:—

"The above list of municipal electric light undertakings shows, however, that the public supply of electric current is no longer a matter on which the slightest room for doubt as to its practical success can exist. The results of the last five years' experience have also been to show that the advantage to the local authority in retaining the public supply of electricity in its own hands are very great. In many cases in which supply companies have built up a solid business, such as in the towns of Liverpool, Bath, Southampton and other places, the corporation or local authority are now feeling the necessity for acquiring it, and will generally have to pay more for it than it cost in the first instance to establish it. It may therefore be remarked that it is advantageous that in Plymouth there is no electric lighting company in present possession, and requiring to be bought out, but a clear field exists for establishing a Corporation Electric Station on the best lines. The experience gained in the last five years or more of the financial results of working shows that the business of public electric supply can be carried on with a profit, which is not only sufficient to repay the loan and meet current interest, but which affords a prospect of making a further margin of profit to the advantage of the town. The experience generally has been that the first year of working is sufficient to place the undertaking in a position to pay its outgoing expenses, and that from and after that time increasing contributions are made to the loan repayment and interest fund."

System Suggested for Adoption at Plymouth.

The adoption of an alternating-current supply system, with transformer sub-centres, is recommended, the Cattewater site, a property owned by the Corporation, being considered well adapted for the establishment of a supply station. The station building is recommended to be designed for an ultimate output equal to 30,000 8 c.p. lamps; only about one-third of the station to be erected at first, and provision made in the initial building in generating plant at first only for 7,500 8 c.p. lamps operated at one time, or for about 10,000 lamps connected to the mains. As regards the size of a unit, Dr. Fleming advises the adoption, at first, of one not larger than 75 or 100 kilowatts; the alternators to be direct driven, as at Portsmouth or Leicester, and to generate current at 2,000 or 2,400 volts; the current to be transmitted by armoured concentric cables laid direct in the ground to the transformer sub-stations. Dr. Fleming suggests the adoption of the plan he has carried out successfully at Taunton, where no junction boxes are used at all, and hence no receptacles for the collection of gas, and, therefore, no risk of street-box explosions. This plan consists in making at once, when the distributing cables are laid down, a connection or service to every house. For the distributing mains he recommends concentric lead-covered and steel-armoured cable laid under the pavements, as these are quickly laid and give no trouble.

The Report then proceeds as follows:—"I have considered very carefully the question of supply of electric current for power to private houses, shops, and places of business. As gas in Plymouth has a low price, the supply of electric power will have to compete against gas engines served with cheap gas. I think that this may act to retard the growth of a demand for current for power in the daytime, and it has not been found that the sale of power in small units has progressed very fast in any of the provincial towns. If, however, further inquiry shows the necessity of meeting any demand for power in small units which cannot be met more cheaply by gas motors, then I should suggest for adoption in this case a two-phase alternating-current system, by which current, not only for light, but for power, can be distributed, if required. As regards the frequency of alternations, my own strong preferences are for a moderate frequency, such as 50 periods per second, which has been adopted with success at Portsmouth, Ealing and Derby."

The Report then proceeds to strongly recommend that a day supply be not given at first, and that on the subject of charge the full price, viz., 8d. per unit, should be charged for the units supplied to all lamps which burn one hour or less per day; but that a reduction to 4d. per unit be made for all units supplied over and above the one hour per day for such lamps.

Dr. Fleming states that he holds the view very strongly that whenever a corporation undertakes the electric supply, good street lighting should form part of the scheme. Every ratepayer has an equal interest in good and well-arranged public lighting in the streets, and the adoption of a system of arc and incandescent lighting for the streets is, he considers, an essential matter. Ordinary continuous or "rectified" alternating currents are suggested.

Capital Outlay.

After discussing the matter at some length, Dr. Fleming concludes as follows: "Hence it may be considered that for a well-designed alternating-curent supply station, having a total capacity, say, of 400 kilowatts, and a lamp connection of 10,000 8-c.p. lamps, and spare plant and effective working capacity of 300 kilowatts, the probable revenue would be about £5,000 a year, and the capital outlay about £35,000. On an annual output of 200,000 units it can be shown that the whole operating cost can be brought within £3,500, and thus leave £1,500 to pay the share of sinking fund and interest. . . . The above estimate does not include the arc-lighting plant. The general recommendation I make for this portion of the work is that arc-lighting plant should be established at first for about 90 arc lamps with proper reserve plant. This will require four direct-driven arc-lighting machines, three for use and one spare plant, these being either dynamos or equivalent plant in rectifiers. Separate engines will have to be provided for these arc-light dynamos if adopted, but the steam can be taken from the same boilers which supply the steam for the incandescent lighting dynamos. If the rectifiers are employed no separate engines are required, and, subject to the consideration of tenders, the experience at Portsmouth and other places warrants me in believing that there are strong reasons in favour of employing the rectifiers for the arc-lighting plant."

On the Employment of Refuse Destructors for Power Purposes.

"One question on which I was requested to advise in connection with any proposed scheme for electric lighting at Plymouth is the employment of a refuse destructor for generating steam. In the last eight or nine years widespread interest has been aroused on the subject of refuse destruction in towns, and in connection with the subject attention has been given to the possible utilisation of the power represented by the heat given out by the combustion of this refuse. Very different opinions have been expressed by various authorities on this subject, and I may say at the outset that the greatest caution is necessary in accepting many of the statements which have been made on this subject, and also in applying the experience which has been gained in one place to another.

"As your borough surveyor is, I understand, engaged in collecting information for a report to you on the whole subject of refuse destruction, I have handed over to him a quantity of information which I had collected together, on the subject of refuse destruction and the utilisation of the heat for steam generating purposes. I may say, however, that the broad general result I have derived from the consideration given to this subject is that it would be unwise for the Corporation to embark hastily on any scheme which has for its basis a proposal to establish a refuse destructor solely with the view of generating power for electric lighting. The waste heat from a destructor already existing, or which has to be erected purely on sanitary grounds, may be usefully utilised as an adjunct in generating steam for electric lighting purposes; but the statement which has been made that the ash-bin refuse of towns is capable of being made available and sufficient for the whole electric lighting likely to be required is one which has not at present received sufficient confirmation in fact or experience. The general result derived from the actual experience of refuse destructors is that each cell of a destructor is capable of yielding directly by its waste heat on an average 5 H.P., and that such a cell may consume from 5 to 6 tons of ash-bin refuse per day without the use of forced draught.

"Opinions differ very widely as to the economy and utility of using the forced draught; but if we set on one side exceptional cases, and take the above as an average figure, then it is perfectly certain that an amount of refuse destruction equal to about 30,000 tons per annum cannot possibly yield directly the amount of horse-power required in the electric lighting station at the hour of maximum full load. In order to maintain the 10,000 8-c.p. lamps above suggested something like 500 or 600 H.P. must be available at the time of maximum load, but the direct heat from the refuse destructor of the capacity required for the consumption of the above amount of refuse would not probably amount to more than 50 or 60 H.P. The matter would have an altogether different aspect if the power generated by the boilers of the refuse destructor could be stored. A scheme has been put before the Shoreditch Vestry, in London, for utilising the waste heat of dust destructors in combination with a system of steam storage invented by Mr. Druitt Halpin. This system practically consists of large tanks or boilers, into which the steam from the destructor boilers is passed, and in which water and steam are accumulated under considerable pressure for utilisation at a subsequent time. The experiment of thermal storage and destruction will be watched with great interest by engineers, but it would, I think, be wise to hold back from following on the same lines until some experience has been gained

Digitized by Google

of the safety and economy of such a system of thermal storage in practice.

"The one fact that stands out prominently is that the waste heat of the refuse destructor, furnishing at the rate of 1 H.P. per ton of refuse burnt, if utilised directly, is not sufficient to supply the power required for the suggested electric lighting in Plymouth during the hours of maximum demand. It might, however, be utilised during the daytime or hours of night if the destructor station were placed in contiguity with the electric lighting station.

"I therefore suggest in this connection that the plans of your borough engineer with regard to refuse destruction in Plymouth should hold in view the possible utilisation of the waste heat for part of the power required in the electric lighting station, and that the destructor station and electric lighting station may therefore very conveniently be placed in contiguity on the Cattewater site, but at the same time I hold the opinion that the electric lighting station should be made at first entirely independent, and that the question in the forefront as regards a destructor station should be the sanitary one. There will be no difficulty in making the necessary arrangements to utilise the waste heat from the destructor for steam generating, and using it as far as possible in the electric lighting station, if the two are placed side by side. If subsequently a system of thermal storage enables us to do more than we can at present do by the combustion of the ash-bin refuse, that also can be added, but at the present moment I advise strongly that the electric lighting station be made independent of the other.

"At the present time we are able to refer to a number of schemes which have been proposed for the utilisation of the waste heat of destructor cells, but an examination of what has actually as yet been achieved does not warrant me in advising the adoption of any of the proposals which have been put forward for depending entirely on refuse combustion for the generation of current for electric lighting. As your borough engineer is dealing with the subject there is no need to enter into further details as to the manner in which such waste heat as is available can be employed in raising steam."

On the Employment of Electric Traction in connection with Tramcars at Plymouth.

After discussing the *pros* and *cons* of the conduit system, the overhead trolley system, and accumulator cars, Dr. Fleming sums up as follows: "There is, therefore, little room for doubt that the only practical system of electric tramcar traction at the present moment is the overhead system. If this is carried out with all the precautions and knowledge now available, I do not consider that an overhead system is at all objectionable. The light iron posts which carry the trolley wires can be made available as supports for arc or incandescent lamps in the streets in which they exist, and with proper regard to the construction of this overhead work there is no reason to believe that it would in any way interfere with other traffic or be a cause of complaint by its appearance. As regards the cost of working, a careful analysis of a large number of electric railway accounts shows that the average working cost per car mile, exclusive only of interest on capital, is approximately 6½d. in America and 5½d. in Europe, and that the ratio of working expenses to receipts in both countries is approximately 60 per cent., in contrast to which the working cost per car mile on horse tramways appears to be on an average 10d. per car mile, and the ratio of expenses to receipts over 80 per cent."

Dr. Fleming concludes by stating that his general suggestion as to electric traction in Plymouth is that a careful consideration should be given to the question of operating one line at first electrically in the eastern part of the town by a well-devised overhead system, and that the system of power transmission should be such as to be capable of being extended to lines running out in other directions if the results warrant further extension, the Cattewater site being used. His opinion is, however, that the generating machines necessary for supplying the currents for the electric traction should not be the same as those employed for the electric lighting, though steam for both plants might be supplied in one common battery of boilers.

ELECTRIC TRACTION FOR LEEDS.

A special meeting of the Leeds City Council was held on Tuesday afternoon for the purpose of considering the question of tramway traction.

Alderman FIRTH, as Chairman of the Highways Committee, moved that the report presented by the Highways Committee on the subject be adopted. In doing so he briefly reviewed the action of the Committee that was appointed to consider the matter. It would, no doubt, be understood by the Council that they were not there that afternoon to discuss the question as to whether the tramways should be worked by the Corporation or be let to a company, but they were assembled merely to discuss what kind of haulage should be adopted. The Tramways Committee had neither spared time nor trouble in their investigations. There were no two opinions, so far as Leeds was concerned, that a more humane system of haulage than that by means of horses ought to be adopted for the permanent working of the tramways. As to steam haulage, which obtained in parts of the city, many of the members of the Council came to the conclusion years ago that steam engines in the streets ought not to be tolerated as soon as a better system of haulage could be found. Then the Committee's attention was drawn to a system of haulage with motors worked by oil. After carefully examining they came to the unanimous conclusion not to adopt that. Another kind of traction suggested was by motors worked by gas, and in regard to this also the Committee were unanimously of opinion that it would not do for Leeds. Two kinds of traction then only remained for the Committee to consider—the cable system and electricity. It had been suggested by certain members of the Council, and by other people outside, that the two systems might be adopted in the city—that the cars should be drawn by cable in one part of the city and propelled by electricity in another. In the centre of the city it was thought they might have the cable system and in the outskirts the electric system. It was patent, however, that the two systems could not be worked together. The Committee had to look at this question first of all from the standpoint of initial capital cost and secondly the working expenses. The initial cost of the necessary equipment to work the cable system in Leeds would, it was estimated, be £428,922, and the annual working cost £111,819. These figures were worked out on the basis of giving a 7½ minutes' service to all the outskirts of the town, a 3¾ minutes' service for another part, and for the immediate centre of the city a 1⅞ minute's service. The Committee felt it was only fair that both the advantages and disadvantages of the two systems should be set out in the report presented to the Council. The advantage of cable over electric traction was, in the first place, the fact that for the former no unsightly poles were required in the streets, and no overhead wires. There was, too, less wear and tear by the cable system, and the cars moved with less noise than when propelled from overhead wires. The initial cost for the adoption of the electric system in the city would be £378,499, and the working cost £90,072 a year. These figures, he knew, had been questioned. The city engineer was, in the first case, responsible for the figures. Could the city engineer possibly have any interest in trying to put one scheme before the public in preference to another? An element quite as essential in any system they might adopt as its cheapness was its efficiency. There was no question in the minds of the majority of the Committee that the electric system of haulage was far superior to the cable system. One of the advantages of electricity over the cable was that no central slot was required in the street, upon which horses' feet could skid or bicycle wheels could enter. In the cable system three-fourths of the power generated was used to work the cable itself, if there was not a single car put upon it. Now, as far as electricity was concerned, the power generated could practically all be utilised. Electrical cars, too, could vary their speed, and this was a very important factor. The cable car could not vary its speed, but must travel according to the speed of the cable. Therefore, if a car got behind its time it could not make it up afterwards. The speed of the cable, too, would have to be fixed in accordance with the speed at which the cars in the centre of the city were required to travel. In addition, there was less interference with the streets with electricity than with cable in case of repairs. Again, if anything happened to the cable, the whole system was out of gear, and no car could run until the damage had been repaired. No such thing obtained with the overhead electrical system. If a wire broke in a place, the breakage could be located. Another important feature was that they could not reverse the motion of a cable car, which must proceed to its destination. As to the objections raised to the poles and wires required for the overhead electric system, they could judge by their own experience in Leeds. The Roundhay people complained bitterly when the posts and wires were put up in their neighbourhood; but now, he ventured to say, there was scarcely an inhabitant in that district who would consent to have those posts and wires removed, and the system of haulage changed. It had been stated that cars on the Roundhay Park line weighed no less than 9½ tons. The Committee had had one of them weighed, and found that its weight was only 6¼ tons. But electric cars were now being produced which did not weigh more than 5 tons, and that was not excessive. The large steam-drawn cars in the city were 4½ tons. The Tramways Sub-committee had carefully and deliberately considered this question, and their report had been confirmed by the Highways Committee. The Tramways Sub-committee were all but unanimous in favour of the report, and the Highways Committee were also very nearly unanimous on the question.

Alderman SCURHAM seconded the resolution.

Alderman NORTH supported, having confidence in the Tramways Committee, and believing that the overhead electric system was the

Digitized by Google

best available. He added that he had been in favour of the cable system, but had seen reason to change his view. He hoped that the resolution would be carried, and that they would proceed at once to carry it into effect.

Mr. HANNAM moved an amendment to the effect that the report be referred back to the Highways Committee for further consideration. He was a progressive man and desired to see the best possible system adopted, but he did not think the question had been sufficiently considered in detail. There were systems which had not received attention. He was disposed to regard Wilson's cable, in use in South Staffordshire, superior to anything else. He admitted that in the event of a change of system at some future time it would be easier effected and at less expense if the electric system were adopted, but while recognising the merits of that system, he felt that the erection of overhead wires would be a disfigurement of the thoroughfares. There was no need for hurry in the matter, and he asked that the claims of the cable system he had mentioned should be considered.

Mr. BEAUMONT, who seconded the amendment, contended that the members of the Highways Committee had simply given formal approval of the report of the Tramways Sub-committee in order that the question might come before the Council, and had not thereby pledged themselves to vote for the electric overhead system recommended by the report.

Alderman SCARR urged that they should lose no time in laying down the electric system.

Mr. DENISON pleaded for further delay, and then argued in favour of the adoption of the cable, which he said had always been admitted to be a profit-making system. He suggested that they should provide a cable for the Headingley route, and apply the electric overhead system to the Kirkstall route, and see which was the more satisfactory.

Mr. GRAHAM also supported the amendment, and spoke in favour of the cable system.

Mr. J. F. CARTER opposed the resolution, submitting that the erection of wires would be the ruin of the city.

Mr. TWEEDALE said he was not content to vote for the electric overhead system. He was told by electricians that there was one serious objection to it on the ground that, with a quick service of cars, the metals became charged with electricity to such an extent that the fluid escaped through the street pipes, and found an entrance into the houses along the route. In America, he was informed, thousands of pounds had been expended in efforts to get rid of this defect, but so far without success. It seemed to him that more definite information was required.

Mr. MART said the cable, in his judgment, was out of the question, being far too costly. As a member of the Tramways Committee, he had calmly and without prejudice considered the matter, and was of opinion that if the Council would boldly declare itself in favour of the overhead electric system and carry it out, there would be no cause to regret the step. That would be much cheaper than either the cable or the conduit electric system, and when a self-contained electric car was available there would be comparatively little loss in making the change. Objection was taken to the overhead wires, and those on Roundhay-road were pointed to; but, as had been shown, it was possible to have an overhead installation which was ornamental, and which would facilitate the lighting of the streets by electric lamps. He had heard not a single valid argument which would warrant them in sending the matter back to the Committee.

Mr. BATTLE could not agree that the report of the city engineer was in any way of a biassed character. Mr. Hewson had honestly given to the Committee in the report the result of his investigations. The electric system appeared to be the cheapest, and it was certainly, in his opinion, the most comfortable. No one could desire greater ease than riding in the Roundhay-road cars. The resolution, however, he was afraid, was of too sweeping a nature, and thought they had better wait a little, and consider whether the present receipts from the tramways justified the enormous expenditure suggested in the report.

Mr. SCOTT also supported the amendment, maintaining that the question was too important to be hurried.

Mr. GORDON spoke in favour of the amendment. Although in favour of an electric system, he did not consider himself competent to judge of the merits of the different electrical systems—overhead, conduit, and self-contained cars. They wanted some reliable expert evidence before they proceeded to spend the money suggested.

Mr. LEUTY, M.P., was opposed to going in for samples three miles long.

Alderman WARD said they had had an opportunity of examining the books of the Roundhay Park concern, and of ascertaining the exact cost of its working, and it was upon this information that Mr. Hewson had computed the cost of working the overhead electric system. With respect to the overhead wires, it was not proposed to repeat the arrangement on the Roundhay line. The poles, where necessary, would be put against the buildings, and where the road was wide enough it was intended to have ornamental standards, which would also permit of lighting the thoroughfares by electricity. Here choice must be between cable and electricity, and if cost were considered he could not understand how any member could hesitate in preferring electricity. Those who counselled delay had complained of the delay in bringing forward the report and in proceeding to improve the tramways. In voting for the resolution, members would not be pledged to the spending of the whole of the estimate; it was the intention of the Committee to carry out one section at a time, and if that were done they would have an opportunity of seeing how far the system was successful. At present it was apparent that the overhead system was the greatest commercial success. Mr. Gordon proposed to bring in experts. So many experts had been offering their services that the Committee had found them a nuisance. In the hands of experts they would not know what course to adopt, and he hoped the Council would not accept Mr. Gordon's advice. He should certainly vote for the resolution.

Mr. HENRY, who supported the resolution, asked, if decision in the matter was to be delayed, what was to be done with the worn-out tramway tracks? At present, thousands a year were being spent on these, and if there was to be further delay, that waste must go on. He could not see that anything would be gained by waiting until after the forthcoming municipal elections had taken place, for the new members would require some time to become informed in the matter, and when they had obtained their knowledge it might be said that November was again drawing near. It was clear that the Council might for ever delay settlement if that were to be a reason for doing so.

Alderman FIRTH, in his reply, pointed out that harm might arise from delay, because several miles of the existing lines were exhausted. It was scarcely safe to travel on the Chapeltown route. They were now spending at the rate of betwixt £4,000 and £5,000 a year in simply patching those old lines, and if those were relaid they would be relieved of such expenditure. As to calling in experts, he said every expert had his own fad. A committee of experts would not present a report in 20 years. So far as the Committee were concerned, not a single man of them had entered upon his investigations with a bias on his mind. They had come, he believed, to a wise conclusion, and he asked, in the interests of the city, to let there be no further delay on this question. Whether they preferred cable or electricity, do not let them delay the matter any longer.

The amendment was then put, and was lost by 24 votes to 29 votes.

Mr. WILSON then moved a further amendment that the report be adopted, and that it be an instruction to that Committee to forthwith extend the Roundhay electric tramways to the park and centre of the city on the conduit system, with a view to testing its value.

This was seconded by Mr. MOSES GAUNT, but Alderman Firth assuring Mr. Wilson that it was the intention of the Committee to proceed in the first place with one short length of conduit as an experiment, Mr. Wilson withdrew his amendment.

The report was then adopted by 40 votes to 11 votes.

The Leeds Corporation Highways Committee have lost no time, after the adoption of their report by the Council, in advancing the question of the future tramway haulage one step further. On Wednesday afternoon a meeting of this Committee was held in the Council Chamber, and instructions were given to the Tramways Sub-committee to make arrangements for carrying the resolution into effect. It was suggested that the overhead wires from Sheepscar should be extended to the Dispensary, in North-street, and that an electrical conduit be laid from there to Boar-lane. A thorough test, it was argued, could thus be made of the practicability of the overhead and conduit systems being worked in conjunction with each other. However, the matter rests with the Sub-committee to make recommendations. Before the meeting concluded a hearty vote of thanks was accorded to Alderman Firth, the chairman. The resolution was moved by Alderman Ward, seconded by Hannam, and supported by every member of the Committee.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October 5, 1895.*

Parsons' Turbine in America.—The Westinghouse Electric and Manufacturing Company has announced that it has purchased exclusive rights for the use and manufacture of the Parsons steam turbine in the United States.

The Buffalo-Niagara Franchise.—The matter of the franchise granting the Niagara Company the privilege of selling electric current within the city of Buffalo is not yet definitely settled. Several weeks ago the committee of the City Council in charge amended the franchise originally offered so as to meet, it was thought, all the objections of the Niagara Company, extremely great concessions being made for this purpose. This week, however, the franchise was again rejected, and the demand made that the compensation to the city should be reduced from 5 per cent. to $2\frac{1}{2}$ per cent. of the gross receipts. When the framing of the franchise was first undertaken by the Buffalo authorities it was apparently thought that the Niagara Company was in a defenceless position, and very onerous conditions were incorporated in the first draft of the measure. Somewhat to the astonishment of the Buffalo people, it was then found that the Niagara Company appeared to be quite indifferent about transmitting power to Buffalo, and after a time the efforts made in building up a manufacturing city in the neighbourhood of the Falls brought the Buffalo people to realise that perhaps they were the ones to act the part of suppliant. This seems to be the position they have now assumed, and the attitude of the Niagara Company is considered by many people to confirm their belief that the talk of transmitting the power of Niagara to a distance was a mere blind—the Niagara enterprise being primarily a land-jobbing scheme, which expects to derive profit, not from the electrical plant in itself, but in leases and rentals from the vast landed property which it possesses in the immediate vicinity of the power house, and now being developed as a manufacturing centre.

Prof. Forbes and the American Press.—The article by Prof. Forbes in *Blackwood's* has been receiving surprisingly wide attention from the newspaper Press of this country, and the comments printed are not, to say the least, favourable toward the Professor of the claims made as to his share in the success of the Niagara scheme; it should be added, however, that the matter of the article is scarcely considered by the newspaper writers from a technical standpoint, notwithstanding the conclusions arrived at. The many unfortunate remarks made about America and Americans in the article have been resented in an old-time "spread eagle" style, and it is not too much to say that Prof. Forbes at the present time is perhaps more unpopular in America than any Englishman has been for a generation.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It seems to me that the success of the volt, ampere and ohm as practical units of E.M.F., resistance and current respectively is due not more to their being of convenient values for everyday requirements than for the fact of their simple relationship. For one person who requires to know the relationship of these units to the C.G.S. system there are ten who use them without thought or knowledge of their derivation.

If names must be given to units, I heartily agree with Prof. Thompson that the C.G.S. unit should be the ones named, using prefixes "kilo," "mega," &c., for if one must hark back or forward through 10^x intervals when making a calculation, it is convenient to have x indicated beyond doubt in the prefix, instead of having to recall it with an effort of memory, or even perhaps to look up some reference.

Reverting for a moment to Prof. Lodge's letter in your issue of September 6th, I was somewhat amused, when—thinking I would knock the bottom out of his argument for simple multiples by suggesting that he should take one or two seconds less instead of exactly three weeks—I found that his 15,834,000 seconds equals not three weeks, but exactly 26 weeks 1 day 6 hours 2min.! Did the Professor then write a random number of seconds, or has he unwittingly taken one of the precious simple multiples with which our practical system of weights and measures abounds which properly belonged to some other system? (Those of your readers who have time to spare might try whether 15,834,000 is divisible by 4π or any function thereof!) Seriously, 15,834 *mega* seconds would not be an inconvenient expression, were it not that in this special case it would be convenient to know how many weeks and days (the relation between which has been unalterably fixed for us) were represented in the time.

Referring again to Prof. Thompson's speech at the B. A. meeting, is there any reason why we should not compound the prefixes thus: de-mega, cent-mega, mil-mega?

Stress has been laid upon the necessity for distinguishing between **H** and **B**, and I fully recognise the convenience of doing so; but are not such distinctions in reality relics of the "action at a distance" idea? If we suppose a coil of wire in vacuo and an alternate-current sent through it, what generates the E.M.F. of self-induction? The answer is, I suppose, the magnetic lines generated in the ether. Does it not seem, then, that the force and the compression, or whirl, or whatever it may be, are one and the same? Does not the very idea of force distinct and separate from motion, compression, or tension, seem to savour of action at a distance? Still, I admit that the idea of force seems necessary to our present mode of thought.

Returning for a moment to our coil of wire in vacuo. If **B** is defined as that which will generate E.M.F., then we must have a value of μ for ether; and if this remains unchanged when air is admitted, should we not regard air as being magnetically inert or having μ = zero? If **B** is regarded as existing only in what we know as material, then we must regard the ether as material, or else concede that **H** can generate E.M.F.!
—Yours, &c., W. B. SAYERS.

Glenwood, Bearsden.

"INERT" IRON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your Editorial Note at the end of my letter published in your journal, I think that you have misunderstood the meaning I attributed to the word "inert."

The machine was run on open circuit, and no E.M.F. could be obtained. The iron showed no trace whatever of magnetism, and consequently no current was produced.

I believe it is exceedingly rare to find a large mass of iron so completely devoid of magnetism that delicate tests give no indications.—Yours, &c., DAVID SALOMONS.

October 12, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The experience described by Sir David Salomons in your last issue is interesting in that it affords an example of what may occur to any shunt-wound machine under similar circumstances. The explanations offered of the cause of demagnetisation do not, however, appear to be very conclusive.

The more probable cause would appear to be due to the dynamo being switched on to the cells at a time when its E.M.F. was less than the difference of potential at the terminals of the battery. Under these circumstances current from the cells would pass through the armature in the opposite direction to that due to the rotation of the armature, and since the resistance of the shunt winding is great compared with that of the armature, a comparatively small current would pass through the former, but its direction would, of course, still be such as to maintain the original polarity of the field magnets.

When the automatic cut-out acted the E.M.F.'s of self-induction of the *two* machine circuits (armature and shunt) would act in opposition to each other in the armature and

Digitized by Google

shunt winding as one closed circuit. If the E.M.F. of self-induction of the armature is greater than that of the shunt winding, the resultant current would be such as to demagnetise, or even reverse, the polarity of the field magnets.

The same effect would, obviously, be obtained when switching shunt machines in or out of parallel, if the E.M.F. falls below the difference of potential of the 'bus bars.—Yours, &c.,

York, October 15, 1895. J. PIGG.

EXPERIMENTS ON TRANSFER OF HEAT THROUGH PLATES WITH VARIOUSLY-ARRANGED SURFACES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your remarks and useful suggestions in last week's issue on my Paper on the "Transfer of Heat through Plates with Variously-arranged Surfaces," it seems clear that the condensed layer of water deposited on the surface of the plates retarded to some extent the transfer of heat. In the case when copper wire was wound round the cylinder and exposed to steam, it was noticed that the spaces between the coils were full of condensed water which could not easily drain away, and the results showed that the wired cylinder absorbed heat from steam less rapidly than the plain one.

The variation in the effect of the ribs may have been influenced by the difference between the specific heat or capacity for heat of water, air and steam. It may have been possible that when the plain surface was in contact with water that heat was flowing through the plate to nearly its full extent, and any addition of ribs or "feeders" could not materially affect the flow. When, however, the cylinder was surrounded by a medium of considerably less capacity for heat, like air or steam, it might be expected that the projecting ribs or "feeders" would then be able to have effect.

I intend, as you suggest, to try the effect of ribs in liquids of different specific heats, such as oil and melted paraffin wax.—Yours, &c., WILLIAM G. WALKER.

47, Victoria street, Westminster, October 16, 1895.

ALTERNATE-CURRENT WAVE-FORM DELINEATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to point out to you that the method of photographically and automatically delineating periodic curves, described by Messrs. Barr, Burnie and Rodgers in your issue of September 27th, is not new, as the authors seem to think. I described some time ago (see *La Lumière Electrique*, September 12, 1891, and *La Lumière Electrique*, September 16, 1893) a similar arrangement. The only new element is the employment of a mirror actuated by a cam; but I think the rotating drum device preferable for the purpose of photographic recording.—Yours, &c., A. BLONDEL.

[Not only did a detailed illustrated description of M. Blondel's device appears in *La Lumière Electrique* of September 12, 1891, as he points out, but we ourselves published in our issue of October 2, 1891, p. 603, Vol. XXVII., a brief abstract of this article. We must fain plead guilty to an undoubted and inexcusable editorial nod.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We regret very much to learn, for the first time, from the advance proof of M. Blondel's letter, that our curve tracer has been anticipated.

The devices as described in *La Lumière Electrique* have been unknown to the Central Technical College, and of those who spoke of our apparatus and method at the British Association; all have shared our ignorance of the previous similar work of M. Blondel.

With regard to M. Blondel's criticism of the cam: we would point out that the advantage claimed is chiefly for its use in the instrument which *visually* traces a wave. For photographic records a plane screen or a cylinder may be used, as we stated in our Paper.—Yours, &c.,

BARR, BURNIE and RODGERS.

THE MAGNETIC FORCE DUE TO ANY PLANE CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On examining M. Colard's formula for the magnetic force due to unit current in any plane curve, at any point in its plane (*The Electrician*, September 20th, p. 694), I find that it is not correct, at least as it stands.

The formula given is

$$F = \int \frac{ds}{r \rho \cos \phi}, \quad \ldots \ldots \quad (1)$$

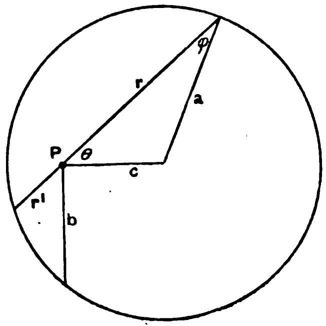
where ϕ is the angle between r and ρ. As mentioned in *The Electrician* of October 4th, I have elsewhere proved that

$$F = \int \frac{d\theta}{r}, \quad \ldots \ldots \ldots \quad (2)$$

and this is not difficult to verify. The formula (1), since $ds = r \sec \phi \, d\theta$, can be put in the form

$$F = \int \frac{d\theta}{\rho \cos^2 \phi}.$$

Comparing this with (2), it obviously does not hold good for a short length of a curve. But possibly (1) was intended only to apply to a closed curve. Its fallacy in this case might be proved generally, but I shall content myself with applying the formula to the case of a circle.



Let a be the radius, c the distance from P, the point where the force is required, to the centre of the circle, θ the angle between c and r, and b half the minimum chord through P, so that $b^2 = a^2 - c^2$.

Then we have $a \cos \phi = \frac{1}{2}$ (chord through P)

$$= \sqrt{a^2 - c^2 \sin^2 \theta}.$$

Hence the integral to be found—namely,

$$\frac{1}{a} \int \frac{d\theta}{\cos^2 \phi} = a \int \frac{d\theta}{a^2 - c^2 \sin^2 \theta}.$$

This can be solved by putting $z = \cot \theta$; the result is

$$-\frac{1}{b} \tan^{-1} \left(\frac{a \cot \theta}{b} \right).$$

This has to be taken for the complete circle; or it may be taken between the limits 0 and $\frac{\pi}{2}$, and the result multiplied by four. We then get, for the force at P,

$$F = \frac{2\pi}{b}.$$

Now I have proved elsewhere that

$$F = \kappa \frac{a}{b^2},$$

where κ is a coefficient having a value varying from 4 to 6·3 (for which I have given a geometrical construction). And it is obvious that the two formulæ are not equivalent.

However, probably M. Colard has merely made some slight slip in his work, as everyone does now and then; and I only point out the discrepancy in order to prevent any misunderstanding on the subject.—Yours, &c., W. H. EVERETT.

THE FILING OF CATALOGUES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have received a letter from the United States Patent Office, asking us for copies of our illustrated catalogues, price lists, circulars, &c., for filing in the library of the Patent Office.

From this letter (of which we send you a copy enclosed) you will see that they have the very laudable object in view of filing these catalogues for reference and "for other purposes," and it has occurred to us whether such a record might not with advantage be procured by our own Patent Office, and so place us on a level with our cousins across the water in having a Government Department for the preservation of this otherwise unrecorded literature.—Yours, &c.,

JOHNSON AND PHILLIPS.

[COPY.]

United States Patent Office.

It is desirable, for purposes of reference, to obtain for the library of the Patent Office copies of illustrated catalogues, price lists, circulars and other publications. In many cases, where no illustrations are given, such lists and catalogues are of great service in determining the meaning of words used in the arts, and for other purposes. It would seem particularly appropriate that the library of the Patent Office should be made a place of deposit for this unrecorded literature of the arts, which would otherwise in a few years be lost. Some of the most valuable books in the library are such lists, some of them more than 70 years old. That such a means of preserving for all time pamphlets of this sort is offered should alone be an inducement to all interested to aid in making this collection as complete as possible. Three copies in general should be sent, one for permanent deposit in the library, and two or more for the use of examiners, but all of them to belong to the library, and to be in charge of the librarian. When successive editions are published, each new one should be sent direct to the Library, U.S. Patent Office, Washington, D.C.

Washington, D.C., October 4, 1895.

SIR: Your attention to this circular is asked, and your contribution, so far as lies in your power, solicited.—Very respectfully,

(Signed) JOHN S. SEYMOUR, Commissioner.

To Messrs. Johnson and Phillips,
14, Union-court, Old Broad-street, E.C., and
Charlton, Kent, England.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s. The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions can now be sent in.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many origina illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d.

A SHEET TABLE giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick aper, price 6d.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

'DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

TENDERS INVITED.—Tenders are being invited by the Postmaster-General (*a*) for the supply of red fir telegraph poles, and (*b*) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot. Forms of tenders may be obtained on application to Charles E. Stuart, Controller of Stores, General Post Office, E.C., and tenders must be in by noon on Monday, the 28th inst.

——— The Director of Public Works, Madrid, invites tenders for the concession for the construction and working of a tramway from Madrid to Colmevar Viejo, Chamartin and Rosa. Tenders by the 15th prox. to the Direccion General de Obras Publicas, Madrid.

——— The Saltash Town Council invite tenders for lighting the district by electricity, gas, or otherwise, from the 4th January next. Particulars of the Chairman of the Works Committee, Mr. W. Alford, 3, Springfield-terrace, Saltash, to whom tenders should be sent not later than Saturday, the 25th inst.

——— The Glasgow City Improvement Trustees invite tenders for wiring the New Family Home, in St. Andrew-street, for the electric light. Tenders to the Town Clerk (Sir J. D. Marwick), City Chambers, Glasgow, by the 21st inst.

——— *Extension of Time.*—The Municipal Authorities of Tongres have extended the time for sending in tenders for the electric lighting of the town until November 8th. Tenders to the Conseil Municipale, Hotel de Ville, Tongres, Belgium.

——— The Glasgow Corporation require tenders for the construction of a new line of tramways, commencing at the termination of the existing tramways at Rockvilla and terminating at Saracen Cross, Possilpark; and also for electrically bonding the rail-joints of the above-named tramways. Tenders, not later than 10 a.m. on the 22nd inst., to Sir J. D. Marwick, Town Clerk, City Chambers, Glasgow.

——— Tenders are required for the lighting of Miners' Hall, Ashington, Northumberland. Particulars of Messrs. Boolds and Hardy, Morpeth.

——— Tenders are invited for the lighting and ventilation of the Lowestoft Town Hall. Tenders to the Town Clerk.

——— The Guernsey Railway Company invite tenders for two electric motor bogie cars to seat 80 persons and suitable for the overhead wire system. Particulars from the Secretary.

——— The London County Council require tenders for a lift and two hoists at their Belvedere-road Works. Tenders to the Engineer's Department, County Hall, Spring-gardens, S.W., by the 28th inst.

ELECTRIC LIGHTING SCHEMES INVITED.—The Battersea Vestry offer premiums of £50, £30 and £15 for the best three schemes, reports, designs and estimates for a system of electric lighting for the parish of Battersea. Schemes must be delivered to Mr. W. Marcus Wilkins, the Vestry Clerk, before 12 o'clock (noon) on Thursday, December 12th next.

TENDERS ACCEPTED.—In our last issue we gave the name of the successful tenderers for supplying the South Molton Shirt and Collar Manufacturing Company with generating machinery, wiring the Company's premises for the electric light, &c., as Messrs Newton and Hawkins, Taunton. The accepted tender was that of Mr. F. M. Newton, Taunton.

——— The Shoreditch Vestry have accepted the tender of the British Insulated Wire Company for the supply of high-pressure and low-pressure electric light mains and conduits, and that of Messrs. W. T. Glover and Co. for the supply of additional high-pressure mains. These contracts have been let at schedule price. Messrs. Siemens Bros. and Co., Reid Bros., the Callender Company, W. T.

Digitized by Google

Henley's Company, the Fowler-Waring Company, and the India-Rubber Company also tendered.

TENDERS ACCEPTED.—The Committee of the Staffordshire County Infirmary received 21 tenders for wiring and fitting the Infirmary for the electric light. We give below a list of these tenders, from which it will be seen that the Committee have decided to accept the tender of Messrs. Drake and Gorham, and that a tender was also received from the Stafford Corporation Electricity Works :—

Drake and Gorham (London) (*accepted*)	£397	0	0
Benham and Sons (London)	836	0	0
Hewes, Geary and Co. (Church Gresley)	796	10	9
Spagnoletti and Crookes (London)	677	0	0
Rooper, W. O. (Stafford)	663	15	1
Laing, Wharton and Down (London)	618	0	0
Corlett Electrical Engineering Company (Wigan)	615	0	0
Northern Counties Electrical Construction Company	586	10	0
Fletcher, Hirst and Co. (Burnley)	566	0	0
Anderson, T. S. (Sheffield)	550	0	0
Walsall Electrical Company (Walsall)	523	15	0
Strode and Co. (London)	500	0	0
Stafford Corporation Electricity Works	491	15	3
Fowler, Lancaster and Co. (Birmingham)	475	0	0
Ball (F. W.) and Co. (Bristol)	468	6	0
Waring (S. J.) and Sons (Liverpool)	455	0	0
Lea, Son and Co. (Shrewsbury)	442	0	0
Liverpool Gas Fittings Company (Liverpool)	434	0	0
Paterson and Cooper (London)	381	10	0
Kendal (J. Lomax) and Co. (Liverpool)	380	0	0
Bennett and Druce (Preston)	319	0	0

——— The Harrogate Town Council received 57 tenders for the supply of machinery and apparatus for their electric light scheme, and the following have been accepted :—Messrs. Houldsworth and Sons, Bradford, for boiler-house plant (without brickwork), at £1,516 ; Messrs. S. Z. de Ferranti (Limited), London, for steam alternator plant, and for switchboard and instruments, at £7,428 and £671. 3s. respectively ; British Insulated Wire Company, Prescot, for mains (exclusive of accessories), at £2,931 ; Brush Company, London, for transformers (exclusive of small sizes), at £403. 7s. ; and Southgate Engineering Company, London, for an overhead crane at £190. The tender for meters has not yet been let. The Town Council received some 30 tenders for wiring the Montpelier Baths, and that of Messrs. Paterson and Cooper being the lowest, has been accepted.

TENDERS RECEIVED.—At the meeting of the Electric Light Committee of the Wakefield Corporation on Tuesday last Mr. Robert Hammond's report on the electric lighting tenders was considered. A noticeable feature in connection with these tenders was that the figures of Messrs. S. Z. de Ferranti (Limited) and John Fowler and Co. for supplying the engine-house plant were almost the same, the amounts being £9,102 and £9,091 respectively. Mr. Hammond's report stated that either firm could be relied upon to do the work to the satisfaction of the Corporation, but he left the selection of the type of engine in the hands of the Committee. After considerable discussion the Committee decided to give out the whole of the contract for supplying the works plant to Messrs. John Fowler and Co., Leeds, at the sum of £10,900. The following additional tenders were also recommended for acceptance :—British Insulated Wire Company, cables, culverts and trenching, at £3,192. 3s. 4d.; Messrs. John Fowler and Co., transformers and distributing switchboard, at £448 ; Brush Electrical Engineering Company, arc lamps and posts, at £252. 10s.; Westinghouse Electric Company, meters, at £233. 18s. 3d. ; and Mr. Thomas Smith, of Rodley, Leeds, for an overhead crane, at £253. The whole of these contracts amount to £15,279. 11s. 7d., as against Mr. Hammond's estimate of £15,893, submitted to the Local Government Board.

SALE BY AUCTION.—From our advertisement columns this week it will be seen that Messrs. Wheatley Kirk, Price and Goulty, in compliance with instructions from Mr. D. Ellis, the receiver and manager in the liquidation of Poole and White (Limited), will sell by public auction at an early date that Company's electrical engineering works, together with the valuable and modern fixed and loose plant, &c. Plans and particulars can shortly be obtained gratis from Messrs. Steavenson and Couldwell, 93, Gracechurch-street, or from the auctioneers, 49, Queen Victoria-street, and Albert-chambers, Albert-square, Manchester.

——— Messrs. Percy Huddleston and Co. will sell by public auction on Tuesday, the 29th inst., at the Newton Heath Cable Works, Newton Heath, Manchester, some important plant and machinery, loose tools and utensils of an electric cable and wire works. The sale is announced to commence at 11 for 12 o'clock prompt, and catalogues may be had on application to the auctioneers, 72, Finsbury-pavement, London, E.C., or 20, Chapel-walks, Liverpool. Further particulars appears in our advertisement columns.

REMOVAL.—The Westralian Electric Lighting and Supply Company have removed to 54, Old Broad-street, E.C., where all communications should in future be addressed.

PARTNERSHIPS DISSOLVED.—The partnership business of electrical engineers and boat builders hitherto carried on by Messrs. Martin and Johnson at Strand-on-the Green, Chiswick, has been dissolved.

——— Messrs. T., W. A. and S. R. Malson, who have hitherto carried on business as electric fuse makers under the style of the Patent Electric Shot Firing Company at Chesterfield and Newbold, have dissolved partnership.

BANKRUPTCY DIVIDEND.—All claims against the estate of Walter Andreae, recently trading as an electrical engineer at 47A, Lower Belgrave-street, S.W., must be sent in to the Official Receiver (Mr. G. Wreford), Bankruptcy Court, Carey-street, W.C., by the 23rd instant.

LIQUIDATIONS.—A summary of the statement of affairs and observations in the winding-up of the Proprietary Gold Recovery Company (Limited) has just been issued by the Official Receiver. The order for the winding-up was made on the 17th July last, and the Company was incorporated in July, 1894, with a nominal capital of £150,000, for the purpose of purchasing and developing Mr. J. B. Hannay's patents for extracting the precious metals from their ores, and by an agreement dated July 18, 1894, the Company agreed to purchase these patents for certain considerations, including a cash payment of £5,000. Mr. E. J. Pape, the original promoter of the Company, who was interested in the patent rights to the extent of one-half, made in 1891 an unsuccessful attempt (in conjunction with Mr. Hannay) to form a company for demonstrating the process. In March, 1894, an agreement was entered into between Mr. Pape and Mr. Hannay, under which Mr. Pape had the option of forming a company for the acquisition of the patents. After some time differences of opinion arose between Mr. Hannay and Mr. Pape in regard to certain machinery which was acquired by the Company. The failure of the Company is attributed by Mr. W. Crooks and Mr. W. C. Johnson to Mr. Hannay's refusal to practically demonstrate the method of recovering the gold from the cyanide solution by means of the electric current, while Mr. Hannay states that he was always ready to demonstrate the process if suitable plant had been provided, and he attributes the failure to the depletion of the Company's funds by the Directors in the purchase of plant which was useless for carrying out his process.

——— At the extraordinary general meeting of the Hope-Jones Electric Organ Company (Limited) on September 10th it was decided to wind up the Company voluntarily, and Mr. R. S. Blease, C.A., Fenwick-street, Liverpool, was appointed liquidator.

THE "I.E.C." DRY CELL.—It is now some three years since the first dry cells were put on the market, and nearly every month brought a new type of these batteries into existence. Amongst the new-comers is a dry battery put on the market by the International Electric Company, which they have named the "I.E.C." dry cell. We are told that some of these cells have run as long as 768 hours uninterruptedly, short-circuited on a 5-ohm bell. The same cells having had a rest of a fortnight, were then again run for 343 hours consecutively, and allowing a further interval for recuperation, the cells yielded another output of 104 hours, giving a grand total of 1,215 hours before exhaustion. The International Electric Company are willing to give cells free of charge to any public institution interested in the comparative tests of dry cells.

ELECTRIC CRANES.—Messrs. Glover and Co., of Hatcham Saw Mills, London, S.E., being dissatisfied with manual labour for working the crane by which they stacked their timber, recently adopted electricity as a substitute. The firm found that if they worked the crane by steam power they would have to pay a very much heavier premium for fire insurance. The dynamo which is used for generating the current is also employed in the evening for the lighting of the works and offices.

THE MANUFACTURE OF THE ELECTRIC INCANDESCENT LAMP IN ENGLAND.—Considerable concern was expressed some time ago that foreign competition would soon drive the English-made incandescent lamp entirely out of the market. A visit to the works of the Sunbeam Lamp Company at Gateshead-on-Tyne at once disabuses the mind of anyone harbouring such fears, for to meet the demand this Company have been compelled to make large extensions to their plant. It is well known—to the electrical trade at least—that some few years ago this Company was stopped in their manufacture of high candle-power lamps by an injunction brought against them for supposed infringement of the "master" lamp patents ; but as only about a year had to run before the expiration of these, the Company, rather than enter into a costly litigation, wisely ceased operations. During the interim considerable money was expended in perfecting the factory for the output of smaller lamps, as well as the high candle-power lamps for which they had already gained a name. The composition of the filament used in the "Sunbeam" lamp is a speciality of the Managing Director, Mr. Edmundson, whose con-

Digitized by Google

nection with manufacture of glow lamps since their first introduction gives him an unequalled experience in all the details in the manufacture of incandescent lamps. The spacious building occupied by the Company is, by the way, the scene of Charlotte Brontë's book "Jane Eyre," and was originally the Gateshead Hall, a building of much interest. It is perhaps unnecessary to say that great care is exercised in manufacture, no lamp being passed unless satisfactory in every point as regards candle-power, voltage and efficiency, each individual lamp before finally packing for storage being tested three times. The demand for "Sunbeam" lamps has exceeded the most sanguine hopes of the Company.

ELECTRICAL POWER STORAGE COMPANY (LIMITED).—This Company forward us a circular giving prices and particulars of their new cell inspection lamp, which will prove useful in examining the condition of the larger type of "E.P.S." cells. A 4-volt lamp, supplied with sufficient flexible conductor and spring clips to hang on the lugs of two adjacent cells, is employed. The connections are enclosed in an acid-proof tube, and are so arranged that a new lamp can be easily inserted when required.

CATALOGUES.—We have received from Mr. John Spencer, of the Globe Tube Works, Wednesbury, Staffs., a pamphlet containing prices and particulars of his electric wire and cable tubes, wrought-iron tubular telegraph poles, steam and vacuum gauges, pipe joints, &c. Tables of dimensions are also given.——From the Britannia Company, of Colchester, we receive a circular descriptive of their new "Facile" carriage motor, for which they claim many advantages.

ELECTRO-HARMONIC SOCIETY.—A smoking concert will take place on Monday next, the 21st inst., at the St. James's Hall Restaurant (Banquet Room), Regent-street, London, W., at eight o'clock.

ABERDEEN.—At a recent meeting of the Buildings Committee of the Public Library an estimate of the cost of wiring the building for the electric light was submitted, and at the last meeting of the Town Council the Committee were authorised to proceed with the work.

ALDERLEY EDGE (MANCHESTER).—The District Council at their last sitting decided to sell their Provisional Electric Lighting Order to Mr. S. V. Clirehugh, of Manchester, who is acting on behalf of a company about to be formed for the purpose of lighting the district electrically.

ASHTON-ON-MERSEY.—The Parish Council are making inquiries into the cost of lighting the district by electricity with a view to applying for a Provisional Order.

BATH.—A proposal has been made for lighting the markets by electricity, and a report thereon is being prepared by Mr. A. McTavish.

BOOTLE.—The Town Council have engaged Mr. T. L. Miller, of Liverpool, to report upon the lighting of the town by electricity.

BRADFORD.—The *Bradford Observer* of the 12th inst. contains the following letter anent the change recently made by the Corporation in their method of supplying electric current :—

SIR: I should like to ask, through your valuable paper, if our Borough Electrical Engineer or any of the Gas and Electricity Committee can give a satisfactory reason for altering the town supply from 115 volts to 220. There has already been spent about £50,000, if not more, on this luxury, and, now they have got a good supply, they must start spending more money, and also cause their consumers to do likewise. There were in the town, up to December last, about 37,000 incandescent lamps running at 115 volts. At whose expense are all these lamps going to be changed to 220 volts? I think it will be a great injustice if the ratepayer should have it to do just to suit a lot of men who love spending other people's money. The elections are getting very near now, and I think ratepayers ought to send men who will stop all this tomfoolery in spending money on such things as electricity and oil gas, and utilise it in providing other things that will benefit the town more.—Yours, &c., G. F. K.

Bradford, October 11, 1895.

BUSINESS LECTURES.—The Cowper-street School Old Boys' Club has inaugurated a series of practical trade lectures on mechanical, industrial and commercial subjects. These lectures are calculated to be of service to young men engaged in trade or general business, and visits to the works of some leading firm in each department have been arranged. Further particulars from the Secretary at the Schools, Cowper-street, E.C.

CARDIFF.—The Town Council have now obtained the formal sanction of the Local Government Board to their borrowing £16,385 for electric lighting extensions.

CHELSEA (LONDON, S.W.).—The Chelsea Electricity Supply Company recently wrote to the Board of Guardians, suggesting that the new workhouse buildings should be wired for the electric light, and the communication has been referred to the Finance Committee for consideration and report.

CHELTENHAM.—The Cheltenham Conservative Club was lighted electrically for the first time on Saturday last. The work of wiring and fitting has been carried out by Messrs. R. E. and C. Marshall.

CHICHESTER.—At the last meeting of the Town Council a member took exception to an item in the accounts of £31. 10s. for a report on the electric lighting question, and Mr. Councillor Prior, in explanation, said that when the report was obtained they were considering the subject of the lighting of the district newly-added to the borough area, and it was thought desirable to obtain information as to the cost of electric lighting before they finally decided to adopt gas. He added that the money was well spent, as the gas company reduced their prices to a considerable extent on the receipt of the electrical engineer's report.

COLWYN BAY.—The Urban District Council have decided to apply for a Provisional Order.

CORK.—The Electric Lighting Committee of the City Council have engaged Mr. T. W. Smith, of Messrs. Calvert and Co., Manchester, to advise them on the electric lighting question.

DENBIGH.—At their last meeting the Town Council referred the question of lighting the town by electricity to the Lighting Committee.

DERBY.—Meetings in connection with the scheme for promoting the construction of an electric railway between Derby and Ashbourne, will be held at Mickleover on the 18th inst., and at Ashbourne on the following day. It is reported that there is a very strong feeling in favour of the scheme in Derby and the neighbourhood.

DEWSBURY.—Recently some very successful experiments in cooking by electricity were carried out in the presence of several gentlemen at the Railway Hotel. The Corporation are endeavouring to create a demand for current for cooking and heating purposes in the district, and with this object in view Mr. J. B. Mitchell (the borough electrical engineer) has decided to keep some cooking and heating utensils at the Corporation Electricity Works in Bradford-road for the inspection of the public.

DOUGLAS (ISLE OF MAN).—The Town Commissioners on Tuesday confirmed the draft agreement for leasing the Douglas Bay Tramways for 21 years to the Isle of Man Tramways Company. Under the agreement the Company are authorised to construct and work a cable tramway to Upper Douglas.

EALING (LONDON, W.).—The estimates of the Electricity Department of the District Council for the coming half-year were recently published. The maintenance charges are put at £1,800, while the revenue, based on the number of lamps actually connected to the mains, is put at £1,400. As, it is stated, there is a continual increase in the number of customers, it is anticipated that the revenue will greatly exceed the estimated sum.

ELECTRIC TRACTION.—Mr. W. J. Carruthers Wain (president of the Tramways Institute of Great Britain and Ireland) has again set out on a visit to the United States and Canada for the purpose of making further inquiries into the question of electric traction. Mr. Wain intends to inspect all the newest and most improved methods of traction in these countries.

EXETER.—At the meeting of the City Council on Wednesday last it was decided to appoint a Special Electric Light Committee to take charge of the Electric Light Company's undertaking recently purchased by the Council, and to confer with the Exeter Electric Light Company as to repairs to and renewal of the plant.

FLEETWOOD.—The Board of Trade have extended the time for complying with the terms of the Fleetwood Provisional Order (1890) to March 30th next.

GOVAN.—At Tuesday's meeting of the Govan District Lunacy Board a long discussion took place on the question of the lighting of the new Hawkhead Asylum Hospital. Several members favoured the adoption of the electric light, but on a division a motion for the appointment of a committee to make inquiries into the cost of electric light was lost.

HACKNEY.—At the last meeting of the Vestry the Sanitary Committee's report, which recommended the adoption of a combined electric lighting and refuse-destructor scheme for the parish, was, after a short discussion, adopted.

HAMPTON WICK.—The Lighting Committee are to consider the subject of lighting the district electrically.

HARROGATE.—In another column we give particulars of the tenders which the Town Council have accepted for supplying electrical plant and machinery. At the last meeting of the Council it was stated that £27,000 would be required to complete the electric lighting scheme, instead of £25,000 as originally estimated. The contracts already let amount to £13,202, and the Town Clerk was authorised to borrow £2,000 in addition to the £25,000 authorised at the last meeting.

HUDDERSFIELD.—The Electric Lighting Committee have decided to reduce the charge for electric current for cooking purposes to 2½d. per unit, and at the last meeting of the Committee the borough electrical engineer (Mr. A. B. Mountain) was instructed to prepare and issue a pamphlet showing the advantages of electricity for motive power, cooking and heating purposes. Instructions were

Digitized by Google

also given to the Town Clerk to obtain the necessary powers to enable them to extend the electric light mains to Longwood.

ILFRACOMBE.—At a special meeting of the District Council last week the question of the purchase of the gas works was under consideration, and, after some discussion, it was decided not to take any further steps in the matter until they had obtained information as to the cost of lighting the town by electricity.

INVERNESS.—Some time ago notices were received by the Town Council from the Caledonian Electric Supply Company and the Municipal Electric Light and Power Company of their intention to apply for Provisional Orders. On receipt of these notices the Council evinced a desire to obtain further particulars of the schemes of these Companies, and the Town Clerk was accordingly instructed to write for particulars. At the meeting of the Town Council last week it was stated that no reply had been received from either Company, and the Council therefore decided to oppose both applications.

KINGSWOOD (BRISTOL).—At the meeting of the Urban District Council on Wednesday it was decided to approve the plans recently submitted by the Tramways Company for the extension of their line to Warmley Hill. Work on this extension was commenced yesterday (Thursday).

LANCASTER.—Mr. A. S. Barnard, who was recently appointed electrical engineer at the Hull Corporation Electricity Works, has now formally resigned his position of borough electrician at Lancaster. The Hull appointment is worth £250 per annum, while the Lancaster Corporation only gave a salary of £120 !

LLANELLY.—At the last meeting of the District Council it was decided that a committee of the whole Council should wait upon Mr. J. C. Howell for the purpose of arranging the terms as to the purchase by him of the Llanelly Provisional Order.

MANCHESTER.—At the meeting of the Town Council on Wednesday a long discussion took place on the motion to receive the report of the Special Tramways Committee. The report recommended the Corporation to apply for powers to work the tramways after the leases expired in 1898 and 1901 respectively. Mr. Vaudrey moved that the matter be referred back for further consideration, as he contended that the question had not been sufficiently discussed in committee, and he thought that before applying for Parliamentary powers they should endeavour to obtain the cooperation of the Salford Corporation, through whose district some of the tramways ran. This course was favoured by several other members, and a long debate ensued. Mr. Southern, who supported the motion, suggested that the Corporation should take care to obtain powers for working the tramways by electricity, steam, or by horses. The proposal of the Committee was ultimately adopted.

MILE END.—The Board of Guardians recently discussed the plans and estimates prepared by their works superintendent (Mr. Burden) for the lighting of the workhouse premises by electricity. The cost of the installation was roughly estimated at £5,000. It was decided to apply to the Local Government Board for their sanction to the scheme, and in the meantime the Clerk was instructed to write to other boards of guardians who had already adopted electric lighting, for information as to cost of installation, &c

MONMOUTH.—Some time ago Col. Ducat held an inquiry on behalf of the Local Government Board into the application of the Town Council for sanction to borrow £20,000 for a joint electric lighting and refuse-destructor scheme, and the Board have now written to the Council, stating that, having regard to local objections to the electric lighting portion of their scheme, they wish to be supplied with additional figures as to the estimated initial outlay on and probable income from the scheme. The Board also ask for more definite information as to the probable income from the sale of electric current, &c., for private purposes. In reply, the Town Council state that the initial cost of an electric light installation, capable of supplying current to an equivalent of 2,500 8 c.p. is £5,600, while the total estimated revenue would probably amount to £1,018. 6s. 8d. In this estimate of income, the Council have altogether omitted the revenue which would be earned by the electric light works if the joint scheme were adopted. This source of revenue is estimated to bring in a further sum of £225 per annum. The principal reason for establishing electric lighting works in conjunction with the sewage scheme was to lower the cost of the latter scheme, and the Council further point out that the electrical machinery could be employed in the daytime to pump the sewage.

MORLEY.—The new Town Hall, which was formally opened by the Right Hon. H. H. Asquith, M.P., on Wednesday, is lighted throughout by electricity. The installation was carried out by a local firm, Messrs. Graham and Chapman.

NEW CABLE STEAMER.—It is stated that the New Zealand Government have placed an order with Messrs. Dunlop and Co., Port Glasgow, for the building of a new steamer, which is to be employed for cable and lighthouse work. The vessel is to be completed within six months, and will cost about £30,000.

NEWPORT.—The Town Council have decided to wire the Free Library buildings for the electric light.

REIGATE.—A special meeting of the Town Council was held on Monday for the purpose of considering the subject of lighting the town by electricity. Notices had been given by Messrs. C. J. Grist and Co., the Guildford Electricity Supply Company and the Town and Village Electric Light and Power Company, of their intention to apply for Provisional Orders. Councillor Powell moved the appointment of a sub committee to make inquiries into the matter and report to the Council, the committee to have authority to employ an electrical expert to advise them as to the cost, &c. A long discussion ensued, and the resolution was eventually carried.

ROMFORD (ESSEX).—A motion by Mr. Westgate that the Council take the necessary steps for obtaining a Provisional Order was, after some discussion, defeated at the last sitting of the District Council.

SOUTHEND.—At the last meeting of the Town Council it was decided to engage Prof. A. B. W. Kennedy to report upon and prepare a scheme for lighting the town by electricity at a cost of 100 guineas.

SWANSEA.—It was anticipated that a long discussion would arise on the electric lighting question at Wednesday's meeting of the Town Council. Mr. Viner Leeder had given notice of his intention to move that the recent resolution of the Council adopting the minutes of the Electric Light Committee be rescinded, but the Mayor ruled this notice out of order. It was, however, stated that some alterations had been made in the original plans of the Committee, and it is expected that this concession will have the effect of greatly minimising the present opposition to the electric lighting scheme.

TELEGRAPH WIRE EXPORTS.—Notwithstanding a slight increase in the activity in the export of telegraph wire and apparatus during the past month, the value of the exports only amounted to £45,268, as compared with £49,820 in September, 1894. The returns for the first nine months of the year show a total of £383,437, as compared with £1,304,594 in the corresponding period of 1894.

THE ELECTRIC LIGHT IN BRAZIL.—It is reported that Cataguazes and the Quarantine Station at Ilha Grande are to be lighted electrically, while work in connection with the electric lighting of the cities of Maceio and Para is making rapid progress; 86 arcs of 2,000 c.p. each, and 1,800 incandescents varying from 16 to 25 c.p. will be employed in the lighting of the latter city, and the generating plant will be capable of supplying current to an equivalent of 10,000 16 c.p. lamps. The whole of the machinery has been supplied by Messrs. Siemens and Halske, Berlin.

WALSALL.—The Town Council have decided to borrow additional money for electric lighting extensions.

WILMSLOW (NEAR MANCHESTER).—At the last meeting of the District Council the electric lighting question was discussed at great length. Mr. Ross moved that the Council take the necessary steps to obtain a Provisional Order, but the gas interest, which happens to be very strongly represented in the Council, succeeded in getting the matter postponed for 12 months.

WOKING.—At a recent meeting of ratepayers in the St. John's and Goldsworth Ward it was decided to adopt the electric light for the lighting of the district, and at the last meeting of the District Council the Surveyor reported that he had obtained a tender from Messrs. New and Mayne, who estimated the cost of erecting lamp pillars at £260, while electric current would cost £4. 4s. per lamp for 2,200 hours, or a total of £168 for 40 lamps. The capital expenditure would be repaid by half-yearly instalments of £44. 18s. 8d. in seven years.

WORKS LIGHTING.—Messrs. Ambrose, Foster and Co., of Leicester, propose to make extensive alterations in their premises, including the introduction of the electric light.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

September 19, 1895.

17,479. C. P. J. FITZSIMON. Dublin. An improvement in connection with electric pushes for hall or other doors, which may be used in connection with or replace existing door knobs, handles, or pushes.

17,481. R. H. BEST. London. Improvements in electroliers.

17,495. V. I. FEENY. London. Electrical heating apparatus. (H. W. Johns Manufacturing Company, United States.)*

NEW COMPANIES, STATUTORY RETURNS, &c.

ROBERT DAWSON AND COMPANY (LIMITED).—This Company was registered on October 8th with a capital of £20,000, in £5 shares, to acquire the business of engineers, iron, steel and brass founders, boiler makers, lighting, heating and ventilating engineers, &c., carried on by Robert Dawson and Company (Limited), at Stalybridge.

ELECTRIC SIGN AND GENERAL ADVERTISING COMPANY (LIMITED).—This Company was registered on October 12th, with a capital of £5,000, in shares of £1 each, to acquire and take over as a going concern the business carried on by Guy C. Fricker, electrical engineer, and Alfred W. Poulton, at 46, Queen Victoria-street, London, E.C., to enter into an agreement with the said Guy C. Fricker and Alfred W. Poulton, and to carry on the business of manufacturers of and dealers in electrical and other advertising apparatus and appliances. The first subscribers, with one share each, are: Alfred W. Poulton, Guy C. Fricker (electrical engineer), F. Miller, G. S. Warmington, D. J. E. Edmonds, W. H. E. Godolphin and F. Huntley. The first Directors are: Alfred W. Poulton (Chairman and Managing Director), and Guy C. Fricker.

WEST AUSTRALIAN ELECTRICAL TRUNK POWER AND LIGHTING COMPANY (LIMITED).—This Company was registered on October 8th, with a capital of £510,000, in 500,000 Ordinary and 10,000 Deferred shares of £1 each, to carry on in West Australia and elsewhere the business of an electric lighting company in all or any of its branches, electricians, electrical engineers, mechanical and general engineers, and electrical apparatus manufacturers; to construct, lay down and establish all necessary cables, wires, lines, batteries, accumulators, lamps, apparatus and works; to generate, accumulate, distribute and supply electricity, &c. The subscribers, with one share each, are: C. G. Kistner, H. J. Kidd, L. Brown, A. E. Dayes, A. W. Boon, B. H. Bourne, and A. H. Skan.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The annual return to October 9th has been filed. The whole capital of £50,000, in £5 shares, has been taken up, and has all been issued as fully paid.

HARRINGTON ELECTRIC LIGHT COMPANY (LIMITED).—The statutory return to October 1st has been filed. The whole capital of £2,000, in £1 shares, has been taken up, and a call of 5s. per share has been made.

I. R. S. ACCUMULATOR COMPANY (LIMITED).—By a recent agreement 50,000 fully-paid shares in this Company have been allotted to Mr. A. W. Stormont, of Old Broad-street, London, E.C., in discharge of a debt of £50,000.

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—An agreement has been entered into by this Company with Edward Clough, of Keighley, Yorkshire (liquidator of the Keighley Electrical Engineering Company, Limited (in liquidation), which provides for the allotment of 1,000 shares (1 to 1,000), each with 10s. considered as paid, in full satisfaction of a debt of £500 owing to the said Edward Clough.

PHŒBUS ELECTRIC BATTERY SYNDICATE (LIMITED).—This Company has entered into an agreement with C. N. Ganzentes, electro-chemist, for the acquisition of his invention and secret process relating to a new compound fluid or charge for portable primary batteries. The consideration is the allotment of 1,500 fully-paid £1 shares in the Company.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, $30\frac{9}{16}$d. per oz. (Oct. 17th). Consols ($2\frac{3}{4}$ per cent.) $107\frac{3}{8}$—$107\frac{1}{2}$ for money, $107\frac{3}{8}$—$107\frac{1}{2}$ for account; $2\frac{1}{2}$ per cent. $105\frac{1}{2}$—$106\frac{3}{4}$ (Oct. 17th). Stock Exchange Settling Days: Consols, Nov. 6th; Stocks and Shares Continuation Day, Oct. 28th; Ticket Day, Oct. 29th; Pay Day, Oct. 30th.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—Letters of allotment for the recent issue of shares in this Company have been posted. It is stated that the new issue was entirely taken up by the present shareholders, more than twice the required amount being applied for.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED). — The accounts of this Company show a profit sufficient to enable the Directors to recommend a final dividend of 3s. per share, making, with previous distributions, a total dividend of 6 per cent. for the year ended June 30, 1895, and also the payment of a bonus of 2s. per share, both free of income tax, which together will amount to £32,500, leaving a balance of £34,410, of which amount £30,000 has been placed to the reserve fund and £4,410 carried forward. The register of transfers will be closed from the 22nd to the 30th instant inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended October 13th were £916, against £920 in the corresponding week of 1894, a decrease of £4. The total receipts for the half-year amount to £12,774, against £12,931 for the corresponding period of 1894, a decrease of £157.

HYDERABAD (DECCAN) COMPANY (LIMITED).—At an extraordinary general meeting of this Company on Tuesday last the chairman (Mr. G. H. M. Batten) said that the Directors were considering a project for utilising the flow of the Kistna River, about 12 miles distant from the Company's mines, as a means of providing cheap motive power for mining and milling purposes. The power could be easily transmitted electrically, and would be much cheaper than steam power.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 13th inst. amounted to £1,118. The amount for the corresponding week last year was £906; increase, £212.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LTD.).—It is stated that letters of allotment for the recent issue of Preference shares of this Company have been issued.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). The sale of electricity by this Company for the quarter ended September 29th, at 6d. per unit, amounted to £7,402, as against £6,935 at the same rate for the corresponding period of 1894.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended October 11th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,248.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided to recommend for the six months ended June 30th last, the payment of a dividend at the rate of 6s. per share on the First and Second Preference, and of 1s. 3d. per share on the Ordinary shares. By an error we stated in our last issue that the traffic receipts of this Company for the half-month ended September 30th were £1,703, as compared with £2,679 in the corresponding period of 1894. The figures for 1894 should be £1,679.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 910. [No. 26. Vol. XXXV.] FRIDAY, OCTOBER 25, 1895. PRICE SIXPENCE.

NOTES.

WE have always held the opinion that, although certain things may be "managed better in France," we could at least claim to be ahead of any other country in the manufacture and laying of submarine cables. If, however, the French Government realise within two years the expectations foreshadowed in the conditions of the contract set forth in another column for a "direct cable of great speed and high transmitting power" between Brest and New York, we shall have to make rapid strides in cable enterprise in order to maintain the position which we have undoubtedly held since the early days of submarine cables.

IT would have been more satisfactory had the actual speed of this projected cable been given. Cables nowadays cannot be considered of high speed with a capacity of anything under 30 theoretical words per minute. Before a cable can be so described it should have the capacity of at least 40 theoretical words per minute; but if the French Company can successfully lay and maintain a cable of 3,400 nautical miles, and get a speed of over 30 theoretical words, they will have accomplished something in cable enterprise beyond anything which has ever been done by any other company. To give these results we estimate that it would be necessary to have a core of about 1,200lb. copper and 1,000lb. gutta-percha per nautical mile, and leaving out of the question the great cost of such a cable, the mechanical difficulties alone would be enough to condemn the scheme. A core of this size would require a much greater number of wires than usual for the outer sheathing, and the difficulties which have already been experienced in laying cables of less than half the size of core would make it an "impossible cable." The great additional weight of such a cable would render it very difficult—if not impossible—to repair in such great depths of water as that in which the projected cable would necessarily be laid. We do not think the French Company can have sufficiently realised the enormous weight of a cable of this capacity and the serious difficulties of transport. Even supposing a cable of this capacity were successfully manufactured and laid, it must be remembered that the speed of thirty words per minute is the theoretical speed. This would not be more than equal to about fifteen code words, and after deducting for preambles, repetitions, &c., the actual number of paying words could not, taking the most favourable view, be more than 10 paying words per minute. A cable of this capacity could not be considered, even viewed from the most patriotic standpoint, "a cable of great speed."

SHOULD the steam from central station boilers be superheated? And, if so, where should the superheater be placed? These questions occupied the greater part of the attention of the speakers who took part in the discussion on Mr. BURSTALL's admirable Paper on "The Electric Lighting of Edinburgh," which was read before the Institution of Mechanical Engineers last Wednesday. With characteristic up-to-dateness, and no doubt profiting by his experience at Glasgow, Prof. A. B. W. KENNEDY has placed steam superheaters in the flues, to reduce the liquefaction of the steam in the pipes. Up to the present, as the Professor confessed, these superheaters appear to have done little else than superheat the unfortunate people over the boilers whose duty it has been to look after the thermometers. But this will soon be changed as much as good non-conducting lagging can change it. Most of the speakers were in favour of superheating of some sort; but opinions were divided as to whether the superheat should be derived from the boiler furnace gases or from a separate furnace. The advantage of a separate furnace is that the steam can be superheated independently of the condition of the boiler fires; for it is usually the case that most superheating is wanted when the boilers are making, and the engines are taking, very little steam. The Edinburgh superheaters are placed in a very late part of the boiler flues, where the furnace gases cannot ordinarily be above 800°F. One speaker thought such a "superheater" might only be "a disguised water trap," and doubted if the steam derived any heat therein. Without doubt, the best place to superheat the steam is in a forward part of the flues, where it can get heat first-hand; but there is considerable risk in placing a superheating apparatus in such a place, owing to the difficulty in getting at it, and the impossibility of cutting it out if anything goes wrong.

ANOTHER question which came up for a goodly share of discussion was the relative merits of steam and electrically-driven feed pumps. The latter are used at Edinburgh, but no tests of their efficiency in regular work have yet been made. The steam pump came in for the usual amount of execration, and was dubbed a perfect "steam-eater." Why "eater"? One non-electrical man made a faint defence of it, by saying

Digitized by Google

that if the exhaust steam from the donkey engines is sent into the feed heater there is not a great loss of heat. On the other hand, an experienced chief engineer at one of the oldest electric supply stations in London solemnly declared, that if we work out the economy from the electrical or the steam side we can make the electrical or the steam pump appear the more economical, as we may desire! Cooking of this sort makes one disposed to think that that engineer has been reading the Edinburgh superheater thermometers! Seriously though, there is no doubt that, as he meant to convey, *a priori* calculations and estimates are practically worthless; and the question will only be settled when we can compare the figures representing some months of running of each kind of feed pump under conditions sufficiently alike.

In the course of his remarks Mr. Geipel gave an interesting datum for the loss of heat from exposed steam pipes and flanges, which, as Prof. Kennedy said, "we should all lay to heart." It appears that from each square foot of bare metal surface of pipe or flange, under steam, there is dissipated heat at a rate equivalent to the consumption of half a ton of coal per annum. The need for careful and efficient lagging could scarcely be emphasised in a better way; unless, indeed, the pictorial illustration described by Prof. Kennedy can surpass it. The professor stated that he had noticed that when the shadow of a long steam range was projected upon a white-washed wall by arc light, the lines of the lagged pipe were firm and steady, whereas the outline of each bare flange in the pipe was blurred by a violent commotion of uprising currents of heated air. This is a very tangible expression of the leakage of that half-ton of coal per annum of which Mr. Geipel gave warning.

To those who are still interested in the Magnetic Unit question, we commend for perusal the remarks made theron by our American contemporary the *Electrical World*. Whether or no these criticisms represent the deliberate opinion of scientific men and dynamo-designers across the ocean we cannot say; at any rate they strike us as exceedingly just, not to say exceedingly obvious. "Ill blows the wind that profits nobody," and amidst the confusion which seems likely to arise from the conflict between the English and American proposals, the peaceful Briton may console himself that at any rate a few more years will roll before he is called upon by the unanimous voice of the leaders of electrical science all over the world to adopt a system of units and names for which he has never expressed any decided desire.

The whole of this Magnetic Unit controversy is an amusing instance of the way in which mere vociferousness carries the day, even in the calm circles of science. The practical man, taking his cue, as he should do of course, from his scientific superiors, submissively and gratefully adopted the pure C.G.S. system of magnetic units for his designing work as soon as magnetism became an article of commerce; the only emendation made by him being the adoption of the "ampere-turn." Under the circumstances, therefore, one would have thought he might well have been let alone. There seems, however, every likelihood that he will be ultimately forced *nolens volens* to use names and units he has never clamoured for and would rather be without. Such is the irony of fate! Of course, had the practical system sanctioned by usage been a mere mass of irrationality, scientific men would have had the weight of argument to oppose to the dead-weight of custom. But in this case the system sought to be overthrown is one of science's own devising, and one which "practicians" have for once in a way found tolerably suitable for every-day use.

We are told by our New York contemporary that "*The Electrician*, which had always expressed itself in opposition to specific names for magnetic units, in summing up a recent and extensive correspondence on the subject in its columns, frankly admitted *a strong drift of opinion* favouring such names." The italics are ours. What we *did* say was as follows:—"The correspondence in our columns is a proof that, while there exists a strong feeling against tampering with old units or coining needless new ones, there apparently is some need for names to fit those actually in use. . . . While objecting to the wholesale creation of fantastic names, and units of more than doubtful utility, we are ready to admit that something like a case has been established for recognising by a definite name the unit of magnetic flux."

From the moment when liquid air proved such a valuable agent for producing extremely low temperature in scientific research, it has been evident that, if only certain great difficulties could be surmounted, it might find a large sphere of applicability in commerce. But these difficulties seemed insuperable, and not the least of them was the fact that it is impossible to keep liquid air at ordinary temperatures, because these are above the critical temperature of liquefaction. In all the experiments conducted by Prof. Dewar and others, the liquid air has been kept well exposed to the atmosphere, and has automatically maintained its liquid state and its extremely low temperature by virtue of its gradual evaporation. Were a quantity of the liquid to be sealed up in a vessel, it would rise to the temperature of the surrounding air, and would *de facto* cease to be liquid. It would pass through the critical state and become gaseous. We will not stay to contemplate the enormous strength and thickness of a cylinder capable of holding air in such a state of compression, nor the civil regulations which would have to be enforced if such a cylinder was not to become a more terrific danger than any infernal machine. But it is indisputable that, if it is to become an article of commerce, liquid air must have some better vehicle than such as would be afforded by open pint pots with vacuum jackets.

It was reported in *The Times* last Monday that Herr Linde had succeeded in making liquid air on a commercial basis, and by a novel process. By a succession of compressions, coolings and expansions, the coolings being effected by expanding a portion of the compressed gas in a jacket surrounding the other portion to be further cooled, a succession of decrements in temperature is produced; until, when the critical tempera-

Digitized by Google

ture is reached, the air is liquefied by a final compression. It is claimed that in the process the air grows richer in oxygen, and at length contains some 70 per cent. of this constituent. What becomes of the nitrogen, and how it is got rid of, are not specified. We have little doubt that Herr LINDE can liquefy air in this way; we have greater doubt about the cost of the liquid so produced being reasonably low; but the chief question in our minds is: How will he keep it?

A PARAGRAPH which affords internal evidence of external inspiration has been lately perambulating. It concerns an electrolytic cell known as the Hargreaves-Bird, designed for the decomposition of common salt. Published accounts are somewhat involved, but as far as their import can be gathered they may be summarised thus: The cathode is quasi-amphibious, and its aerial fraction permits the employment of some gas, such as carbon dioxide, which by its combination with one of the essential products of electrolysis—caustic soda—lowers the critical voltage of the cell. It is true that the product at the cathode—viz., sodium carbonate—is relatively and absolutely less valuable than caustic soda, and thus the advantage of a lowered critical voltage is at least compensated. The figures quoted are of the usual misleading kind; an efficiency of "80 per cent." is claimed, by which the wise understand a reference solely to amperes; volts, we suppose, cost nothing. Taking the published estimate of voltage at 3·5, the true efficiency drops at once to 50 per cent. or under, which is precisely that generally found to obtain with most electrolytic processes. Of more importance than the claim to an exceptionally high efficiency is the statement that the exposed cathode allows the oxidation of the hydrogen which accompanies the caustic soda under normal conditions of working. But if this be true the critical voltage should drop correspondingly, and there is no evidence that this occurs. As a matter of fact, we should require unusually good experimental evidence to induce us to believe that any oxidation whatever takes place. On the whole, further information would not be supererogatory.

WE have been informed, in connection with the remarks made in our leading columns last week anent the recent exhibition of horseless carriages at Tunbridge Wells, that no effort was spared to make the show a thoroughly representative one; but either owing to lack of time, lack of faith in their own devices, or lack of patriotism, the inventors of carriage motors other than the Daimler failed to respond. With regard to the steam-horse, about whose exploits we made some comments, we learn that the one which was to have been exhibited could not be completed in time, and, in order not to disappoint, an old one, made many years ago, was sent. A new type, which is said to drop no cinders and emit no steam, will shortly be ready. As a first attempt, the exhibition certainly did credit to the energetic initiative of its promoter.

Electric Traction in Germany.—It has been decided to adopt electric traction on the tramway between Nuremburg and Furth.

A Large Gas Engine.—A large gas engine has, says the *Gas World*, been made in Rouen; 320 indicated horse-power with fuel gas, and 450 with coal gas.

James Forrest Lecture.—The next "James Forrest" lecture, at the Institution of Civil Engineers, will be delivered on Thursday, May 7th, by Prof. A. B. W. Kennedy. Its subject will be "The Applications of Science to Engineering."

Cable Interruptions and Repairs:—

	Date of Interruption.
Cadiz-Teneriffe	Sept. 25, 1895.
Maranbarn-Para	Oct. 10, 1895.

Electric Lighting Charges in Berlin.—On January 1, 1896, a new tariff of charges for current will come into force, by which the present system of charging will be greatly simplified, though only a slight reduction on the original figures will be made. For lighting the price per unit will be 7·2d., but for power the price remains at 2d.

A Correction.—In our issue of the 11th inst., in announcing the death of Herr Eugen Langen, we mentioned that the deceased was part proprietor of Felten and Guilleaume. This firm inform us, however, that Herr Langen was in no way connected with them. The sole proprietors of the firm are the sons of the late F. C. Guilleaume.

Isle of Man Tramways.—It has been ramoured that the Isle of Man Tramways Company intends to purchase the steam line between Douglas and Peel, and to convert it into an electric line; also that it contemplates the extension of the Douglas-Laxey line to Ramsey, thus making a through communication by electric railway between Ramsey and Peel.

Unprecedented Bell Telephone Output.—The record-breaking net increase in the Bell Telephone output, 12,659 instruments for the month ending September 20th, as compared with 2,568 for the corresponding period a year ago, furnishes, says the *Electrical Engineer* of New York, one of the best indications of general trade improvement. The total number of instruments outstanding is 649,219, as compared with 575,223 last year.

Electric Locomotives for Great Altitudes.—It is stated by the *Western Electrician* of Chicago that a representative from the Baldwin Locomotive Works, with an expert electrician from the Westinghouse Company, together with Sir Henry Tyler, ex-president of the Grand Trunk Railway, will shortly start for Peru, where, it is said a test of the feasibility of the electric locomotive is to be made upon a railroad 15,000ft. above the sea level.

Accumulator Cars in New York.—The storage battery cars which are to be tried on the Second and Fourth-avenue Railways in New York are to be equipped with chloride batteries, which will be put under the car, and so placed that the shifting of batteries can be done expeditiously. The work is being carried out by the Electric Storage Battery Company of Philadelphia, which now controls the important United States patents on storage batteries. It is hoped to reduce the cost of handling and maintaining the batteries in service to 1½d. per car mile.

South-West London Polytechnic Institute.—The organisation of this, the newest of London polytechnics, has been brought almost to completion under the direction of Mr. Herbert Tomlinson, F.R.S., the principal, and a programme of useful work in technical instruction has been arranged for the forthcoming winter session. The scientific, artistic and domestic sides of life are well provided for, the last chiefly for the girl students, who receive, among other things, instructions in "Housewifery," and doubtless are awarded valuable certificates in this eminently practical subject.

American Opinion of the Bristol Line.—The *Street Railway Review*, of Chicago, has brought out a "Montreal Convention" number, in which there is much local colour. Our contemporary confesses that "there are a number of interesting features" about the Bristol electric tramway, "and it can even give American roads some pointers in some respects." Our contemporary states that the Bristol line is "the first one built under the new ironclad regulations." We have heard of cast-iron regulations, but perhaps our contemporary thinks these too brittle. Surely, if regulations are ironclad, it must be because the core is soft and weak!

Digitized by Google

Visible Radiation and Temperature.—A new determination of the lowest temperature at which a hot body becomes visible is published by Sgr. Pettinelli, in tho *Nuovo Cimento.* He heated a cast-iron cylinder, 30cm. long and 14cm. broad, in a wrought-iron jacket over a Bunsen burner to a temperature of 460°C., as indicated by an air thermometer, and then observed its flat end in a dark room from a point 60cm. above it. When it had cooled to about 415deg. the red heat vanished and gave way to an indefinite hazy glow. This glow completely disappeared at 404deg., and repeated observations gave an error of only 3deg. Highly emissive substances, such as the "mantles" made by Auer and others for incandescent gas lighting, became visible at the same temperature; but reflecting surfaces had to be heated 20deg. higher before they appeared to the eye, and glass still more. These low temperature rays were found to traverse glass and water like ordinary light rays, but they suffer a comparatively greater absorption. Different eyes differ slightly in their capacity of seeing them; the maximum divergence being about 6deg. But then the extent of surface must be the same. Sgr. Pettinelli found that if he screened off all but $\frac{1}{10}$th of the surface, the body had to be heated 6deg. higher than before to become visible. Hence he concludes that the contradictory results obtained by previous experimenters are due to differences in the areas of the hot bodies investigated.

Car Heating by Electricity.—In a Paper read before the Street Railway Association of New York, Mr. J. F. McElroy discusses the subject of car heating by electricity, and gives a number of useful data. He objects to embedded resistance wires, on the ground that the powdered fire-clay or other embedding material will necessitate a higher temperature in the wire and will thereby increase deterioration. Exposed iron wires are advocated, and if these are kept below about 400°F. no difficulty will be experienced from oxidation. Iron is recommended on account of its high temperature coefficient, whereby any excessive rise in temperature tends to check a further rise by considerably augmenting the resistance and diminishing the current. With German silver this automatic control is less marked. Inasmuch as a car passenger (a standard one, we presume) liberates 191 British units of heat per hour, it follows that the cost of an electric car heater will be less in a crowded than in a comparatively empty car. Moreover, an element of economy exists in the care which, on chilly days, a conductor may take to close the car door promptly after the passage of a passenger. The cost of heating a car in winter time averages 17·6 cents (about 9d.) per day of 15 hours for electrical energy alone. The aggregate cost of heating a car by coal stoves, including attendance, averages 19·25 (about 9½d.) per day of 15 hours.

A Plea for Electric Railways.—There is a remarkable article under this title in *Electrical Engineering*, of America. The author sets himself the task of proving the national necessity for electric railways. He finds a resting place for the vertex of his inverted pyramid in the opening assertion that "the desire for a home is implanted almost as strongly in the human breast as the instinct of self-preservation." Then follow two stanzas from "the Poet Laureate" to show that a man who has a home will have to work for it. Next comes the reflection that when a man has a home he will sometimes want to "go home," and "it is here that the street railway and particularly the electric road offers a solution." Country cousins who flock to the cities must not merely be housed, but "if America is to shun the examples of Greece and Rome, and escape their fates, they must be *homed.*" It was "a French discovery originating in the classic experiments of Marcel Duprez" (*sic*) which renders it possible to go home by electricity. Then follow a number of curves to show how many people go home, and how many miles they go, and what they pay. After all this comes another classic allusion, with the terrible reflection that in the present imperfect means of transit is "the handwriting on the wall, behind which, if unheeded, lurks as grim and inexorable a fate as that which stood in the Chaldean banquet hall; for the public, like the mills of the gods, grind fine though slowly." Surely no municipality can be found to resist such arguments as these.

A New French Transatlantic Cable.—As we have already announced in our issue of October 4th, M. André Lebon, Minister of Posts and Telegraphs, will immediately lay on the table of the Chambre des Députés a Bill concluding a contract with the Compagnie Française des Câbles Télégraphiques for the establishment, maintenance, and working of submarine telegraph cables between France, North America, and the Antilles. According to the terms of that contract, the French Company undertake—(1) To lay within a maximum period of two years, between Brest and New York, a new and quite direct cable of great speed and of great transmitting power; (2) to maintain in good working order, or, if wanted, to replace the present Brest-St. Pierre and New York cable, called the "P. Q." cable, thereby duplicating the line of communication. "This first considerable result," says *Le Temps*, "which gives every security to our relations with America, and will constitute an outlay estimated at £1,200,000, will be carried out in consideration of a yearly subsidy of 800,000fr. (£32,000), which may eventually be reduced when the traffic receipts reach 1,650,000fr. (£66,000) by the application of two-thirds of the receipts to the benefit of the Treasury, the subsidy to cease altogether when the traffic amounts to more than 2,850,000fr. Moreover, the Company will be bound, without any further Government subsidy, to extend the French transatlantic lines to the Antilles by a new cable from New York to Puerto-Plata, connecting at that point with the cable system already owned by the concessionary Company, which serves our colonies. The correspondence of the metropolis with our Antilles colonies may then be transmitted by cables exclusively national."

Buffalo and Niagara Falls Electric Railway.—The present Buffalo and Niagara Falls Electric Railway has just completed a double-track railway from the Buffalo City line to the City line of Niagara Falls, which was opened for business last month. Some interesting particulars of the line are given in a recent issue of the *Electrical Engineer* of New York, from which we quote the following:—"The line is 14½ miles long, and passes through the villages of Tonawanda, North Tonawanda, and Lazalle. The Company charges 50c. for a round trip from Buffalo to Niagara Falls, including transfer over the electric railways both in Buffalo and Niagara Falls. The track construction is of the most substantial kind, 73lb. girder rails being used. These rails have been laid in 60ft. lengths upon white oak ties 8ft. long, 6in. thick, and 9in. wide. These ties are placed 2ft. between centres, and the track for its entire length is ballasted under the ties, 2ft. outside and between the tracks with crushed stone. Stone ballast is 18in. deep over the entire line, extending from 5in. under the ties to the top of the rails, which are 7in. high. The rails are prevented from spreading by heavy brace tie plates, placed 6ft. apart, and the joints, of which there are only one-half the usual number, are held in place by very heavy angle bars, 36in. long, and secured by eight bolts of 1in. diameter. The bonding throughout has been done with Chicago bonds, besides which the four rails are cross-bonded at frequent intervals. The overhead construction is of the usual kind; wooden poles have been used throughout. The Company expects ultimately to take power from the Cataract Construction Company for the entire line. At present this Company furnishes power for the section nearest Niagara Falls only, which includes about five miles of double track. For supplying the rest of the line with power, a steam plant has been installed, comprising four 125 H.P. return tubular boilers, built for high pressure; two compound condensing Ball engines, and two 200 H.P. multipolar generators, furnished by the General Electric Company. The Company owns, and is now operating, 20 motor cars, each equipped with four "G.E." 800 motors. By special switch, these motors can be operated all in series, or in multiple series, or all in multiple, and these combinations, with varying amounts of resistance in the armature circuits or shunting fields, give a wide range of speed. With motors all in multiple, a speed of 40 miles per hour has frequently been reached, and the Company is now operating its cars daily over a practically straight and unobstructed portion of its road over three miles long at a speed exceeding 30 miles per hour. On Sunday, September 22nd, the road was opened for public travel. During this day, the cars were taxed to

Digitized by Google

their utmost capacity, and many thousands of people along the line were unable to get transportation."

Electric Traction in Rome.—An Italian correspondent sends us the following :—A new electric line has recently come into operation. It belongs to the Tramways Company of Rome, and is of special interest on account of the power being derived from an alternating current supply. The line, which is nearly three kilometres long, double track, connects the main railway station of Rome with the centre of the town. The maximum gradient is about 7 per cent. for a length of 500 metres, the remainder of the line being practically level. The sharpest curves have 15 metres radius. A five-minutes service is carried out by seven cars, which take 12 minutes one way and 13 or 14 minutes on the reverse trip. The cars are of the closed type, with two internal and two external platforms, and weigh seven tons empty, the stated capacity being 16 passengers seated and 24 on the three platforms (the fourth being reserved for the driver); the total number of passengers carried is, however, sometimes as high as 50 or 55, bringing the total weight to 10 tons. The car body, which is elegantly finished and brilliantly lighted, is driven by two "G.E." 800 motors. A series-parallel controller, "G.E." type K, is employed for speed regulation, with an additional switch enabling the motors to be short-circuited, and so act as brakes. In addition two mechanical brakes are fitted, one acting on the wheels as usual, and the other on the rails directly. A system of electric bells is actuated by the lamp current, which enables every passenger from his own seat to easily communicate with the driver. The current is supplied at 300 volts by a single trolley, on the standard overhead system. The whole plant derives its power from the alternating Tivoli-Rome transmission. To obtain the necessary transformation a set of high-speed dynamo-motors, having multipolar field and a single armature connected with two collecting rings on one side, and a communicator on the other side, is installed at the end of the transmission line, and a battery of Tudor accumulators is thus charged. This battery, kept constantly charged, supplies the power to the electric tramway. The electric equipment of cars and overhead work was carried out by the General Electric Company of America; the cars are supplied by Messrs. Miani Silvestri and Co., of Milan, and the generating station was equipped by Messrs. Ganz and Co. The line had to be opened on September 1st. Owing, however, to some difficulty experienced with the working of the rotary converters, horse traction had to be resorted to for some weeks, and the inauguration of electric traction was delayed till September 19th. Everything is now working satisfactorily in this plant, and the receipts are exceptionally high, the cars nearly always travelling full.

Method of Automatic Control for Forced or Induced Draft.—In the September number of *Electric Power* of New York, Mr. Horatio A. Foster, writing on the above, says that for many years power-actuated blowers have been in use for forcing air under the grates of steam boilers, or for pulling the air through the fire and forcing it up chimney, but not until late years has the subject received anything like the attention it deserves. It is quite common to apply forced draft to boilers of insufficient capacity or lacking in chimney area both on land and water, and of late the system has been very largely applied in new plants for the use of cheaper grades of fuel and to avoid the erection of costly chimneys. Where blowers are used essentially for reducing the cost of fuel, it becomes necessary to provide some method of automatic control, for if left to the fireman it is capable of a most uneconomical misuse. When suitable apparatus is provided for automatic control of the supply of air under the grates, then forced draught becomes highly efficient, and such seems to have been provided in the apparatus as designed by John E. Beckman, in which also the blower engine is practically out of the control of the fireman. As the steam pressure rises above a predetermined point, the engine is slowed and less air is forced under the grates and the rise is checked. On the other hand, as the steam pressure gradually falls, the speed of the blower gradually increases, and the air supply is automatically increased according to the demand. This regulation is effected generally by a steam-reducing valve of customary type, so piped that it opens to increase the speed of the blower engine as the steam pressure falls and gradually closes to decrease such speed as the pressure rises. This operation can also be secured by connecting to a damper regulator an ordinary throttle valve in the steam pipes supplying the blower engine. Provision is also made to limit the speed of the blower engine in both directions; that is, the engine is never allowed to stop entirely, as it would if regulated by the device above described, but a by-pass, consisting of a small pipe, is carried around the main regulating valve, and steam is by a regulating valve therein admitted through this by-pass at such a pressure as to maintain the blower at a slow speed when the main valve is shut off. By this means a little air is forced through the grates at all times, keeping the fire ready for an important demand. It will be perceived that by this method the supply of air to the furnace of one or a number of steam boilers is at all times automatically regulated. The fireman has nothing more to do with the matter than to maintain the fires in good condition. So long as he puts on the coal and keeps his fires reasonably clean, the rate of combustion is entirely out of his control and is automatically determined by the demand. Moreover, the changes are made gradually, so that the furnace is not alternately heated hotter than necessary and then cooled lower than necessary. This apparatus has been in use in a number of steam plants in the city of Buffalo for some time with considerable success, so much so that it is now attracting a great deal of attention from steam users and engineers outside that city.

Current Electrical Science.—The last report of the *Séances de la Société Française de Physique* contains some interesting electrical items. At one meeting, M. de Kowalski made some experiments with various forms of vacuum tubes in order to discover the precise nature of the CATHODE RAYS. In an H-shaped tube, with electrodes, the rays passed in one direction only through the connecting tube—viz., from the cathode—and made a phosphorescent patch upon the next wall. An electrodeless tube, with a capillary portion in the middle, when excited by Tesla currents, gave patches at both ends. In both cases the rays were deflected by a magnet. In connection with these experiments, M. Curie described some crucial experiments upon the magnetic deviation of light waves. Light-rays were made to run the gauntlet of a magnetic field of 14,000 units for a length of 20cm., the field having a direction perpendicular to the light-rays. But although a hundredth of a millimetre of deviation could have been seen, no such thing was discovered. On the question of the EFFECT OF MAGNETISATION UPON THE ELECTRO-CHEMICAL PROPERTIES of certain bodies, M. Hurmuzescu has at last, with the aid of the capillary electrometer, obtained consistent results. He finds that iron is always made electro-positive by magnetisation. Nickel behaves in the same manner, but bismuth is made electro-negative. The *Physical Review* contains a Paper on alternate currents with ZIG-ZAG E.M.F. CURVES, by E. C. Rimington. Such E.M.F.'s are, to say the least, rare in actual practice, but Mr. Rimington pleads that some dynamos in the market give an approximation to such a curve, and as he also investigates curves of a square or block type, he may be said to touch the two extremes between which the practical and more or less sinusoidal curve finds its place. Although the E.M.F. goes up and down in straight lines, the current does not do so, except when there is no self-inductance. With ordinary values of self-inductance, say 0·01 henry, the current curve is nearly a sine curve, with its nodes opposite the maxima and minima of E.M.F. In the case of a block curve, representing a constant positive followed abruptly by a constant negative E.M.F, the current curve becomes zig-zag, reaching its maximum at the point of interruption. The same number contains a Paper, by Messrs. Guthe and Briggs, on the ELECTROLYTIC CONDUCTIVITY of the peculiar hydrate of sulphuric acid represented by $H_2SO_4 + H_2O$. It has long been supposed that this has the least conductivity of any of the hydrates of that acid. The authors show that whatever the temperature the minimum depends upon the molecular volume, and always occurs when that is 32·1. The dip in the curve of conductivity and concentration becomes less sharp at higher temperatures. The solid crystals of the substance have a very much lower conductivity, and the curve suddenly jumps up at the melting point, whereas if the liquid is undercooled the conductivity diminishes gradually and steadily.

THE CHARGING OF A CONDENSER.

BY ALFRED HAY, B.SC. (EDIN.).

In his Paper on "Transient Electric Currents," published in the *Phil. Mag.* for June, 1853, William Thomson (Lord Kelvin) first gave the mathematical theory of the discharge of a condenser through an inductive resistance, and indicated the existence of electrical oscillations under certain conditions. Numerous experiments have been carried out in support of this theory, the earliest of which were due to Feddersen, who used the method of the rotating mirror. Since then a very large number of experiments, including the brilliant researches of Hertz, Lodge, and many others, have been adduced as proofs of the existence of oscillatory discharges.

The experiments about to be described are intended as a small contribution towards the already overwhelming mass of experimental evidence as to the existence of the oscillations which take place in the charge or discharge of a condenser when certain conditions as to capacity, resistance and inductance are fulfilled. In many experiments on condenser discharges very small capacities were used, rendering the period of oscillation very short, and hence accurate quantitative work difficult. By using a larger capacity we increase the period, and so facilitate the determination of the instantaneous values of the varying quantities.

In the *Phil. Mag.* for 1892, Vol. XXXIV., p. 389, an account is given by Dr. W. L. Robb of experiments "On Oscillations that occur in the Charging of a Condenser." In these experiments capacities of from 0·1 to 1 microfarad were used. Most of the experiments described are qualitative. The method of experimenting consisted in varying the time of charging by using contacts of very short duration. This was accomplished by the use of two steel spheres, one of which was fixed, while the other was suspended, so that when deflected and let go it impinged on the fixed sphere; the time of an impact was taken as the unit of time. The experiments showed that oscillations occurred in the charge. Towards the end of the Paper some quantitative results are given, obtained by using a Helmholtz pendulum for making and breaking the circuit. But the number of points on the curve is not sufficient to indicate its shape with any degree of accuracy.

If the relations of capacity, resistance and inductance are such that the condenser when allowed to *discharge* does so in a series of oscillations, then the *charging* current of the condenser, as well as the potential difference at its terminals, when a source of constant E.M.F. is applied to the circuit, will also undergo a series of oscillations. In this case the potential difference at the condenser terminals may rise to a value considerably in excess of the charging E.M.F. of the battery.

Let a condenser of capacity C be joined up in series with an inductive resistance r, of inductance L, and let a constant E.M.F. of E units be applied to the circuit. Then we have the equation

$$r\,i + \mathrm{L}\frac{d\,i}{d\,t} + v = \mathrm{E}, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where i stands for the instantaneous current, and v for the potential difference at the condenser terminals. Differentiating (1), we get

$$\mathrm{L}\frac{d^2 i}{d\,t^2} + r\frac{d\,i}{d\,t} + \frac{1}{\mathrm{C}}\,i = 0. \quad . \quad . \quad . \quad . \quad (2)$$

Solving (2), and taking account of the initial conditions that, when $t=0$, $i=0$ and $v=0$, we find

$$i = \frac{\mathrm{E}}{\sqrt{r^2 - \frac{4\,\mathrm{L}}{\mathrm{C}}}}\,\epsilon^{-\frac{r}{2\mathrm{L}}t}\left\{\epsilon^{t\sqrt{\left(\frac{r}{2\mathrm{L}}\right)^2 - \frac{1}{\mathrm{LC}}}} - \epsilon^{-t\sqrt{\left(\frac{r}{2\mathrm{L}}\right)^2 - \frac{1}{\mathrm{LC}}}}\right\} \quad (3)$$

This equation shows that oscillations will occur when $r^2 < 4\,\mathrm{L/C}$, the period being

$$\frac{2\pi}{\sqrt{\left(\frac{r}{2\,\mathrm{L}}\right)^2 - \frac{1}{\mathrm{L\,C}}}}.$$

In order to investigate the action experimentally, a method was adopted similar to that used in some experiments on "Current-Rushes," published in *The Electrician* * about a year ago. The method consists in reproducing an essentially non-periodic phenomenon, or the initial stages of it, in rapid succession, so as to render it periodic by artificial means, and investigating the variation of the quantities involved by means of a Joubert contact-maker.

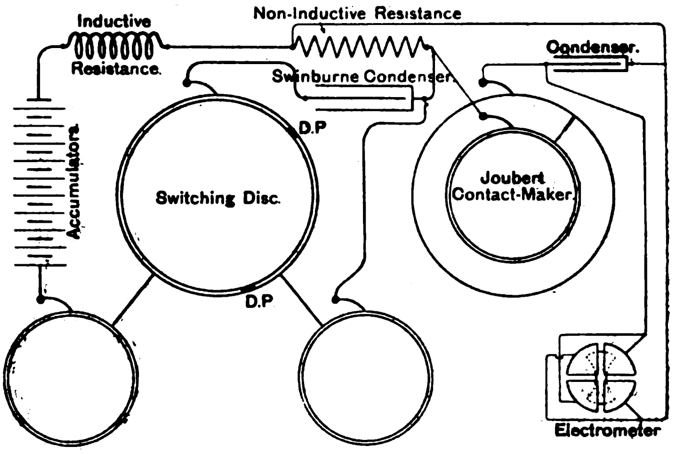

Fig. 1.—Diagram of Apparatus.

The arrangement of apparatus used is shown diagrammatically in Fig. 1. For the sake of clearly exhibiting the connections of the circuits, the various switching discs are shown separately, although as a matter of fact they are all mounted side by side on the same shaft. The discs are made of wood, and one of them, marked "switching disc" in the diagram, is provided with a brass rim divided into two portions by the vulcanite distance-pieces D.P. The smaller discs shown below the switching disc carry simple contact-rings. The discs were

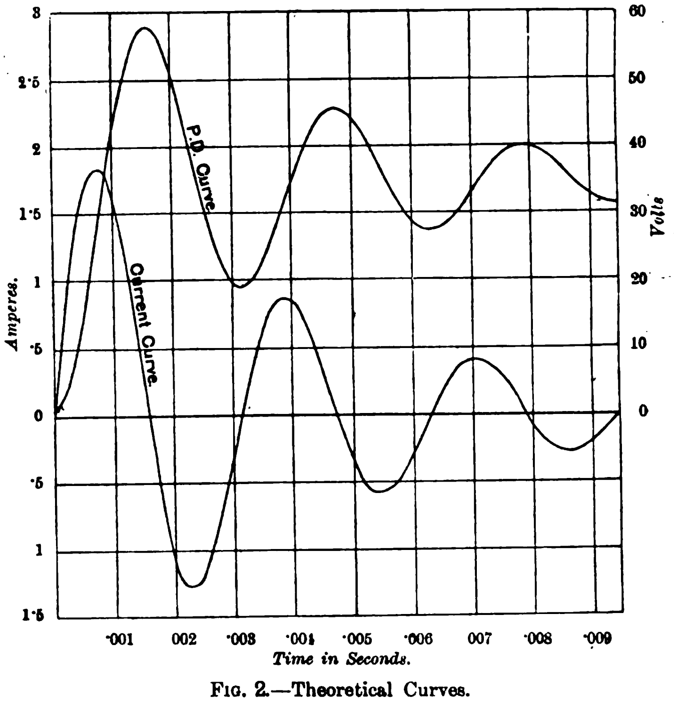

Fig. 2.—Theoretical Curves.

driven round by an electromotor running at a constant speed, and the number of revolutions per minute was determined, so that the time of one revolution, or any fraction of it, was known. Hence the time-value of one division of the scale attached to the Joubert contact-maker could be determined. It will be readily seen, by examining the connections of Fig. 1, that in one revolution of the shaft carrying the discs, the following operations are performed.

* *The Electrician*, Vol. XXXIII.

Digitized by Google

The condenser, discharged to start with, is connected, through an inductive resistance, to the terminals of the charging battery. Contact is maintained for a certain interval of time, during which the condenser is being charged. The battery is next disconnected, and the condenser is short-circuited and discharged. The same cycle of operations is repeated in every revolution of the switching discs.

The instantaneous values of the current are ascertained by having a non-inductive resistance in the circuit, which at definite time-intervals is connected to the terminals of an electrometer shunted by a condenser. Similarly, by connecting the terminals of the condenser at known intervals of time to the electrometer, the instantaneous values of the potential difference are ascertained.

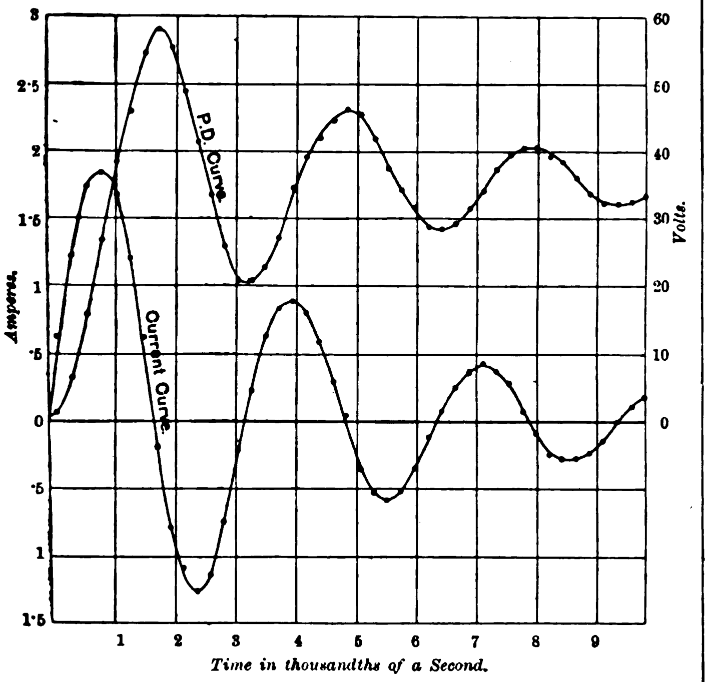

Fig. 3.—Experimental Curves.

In the first set of experiments, the capacity, resistance and inductance of the circuit were so related that the charge was oscillatory. The values of these quantities were:—

$$r=3{\cdot}6\,;\ L=0{\cdot}0076\,;\ C=32{\cdot}6\times10^{-6}.$$

Substituting these values in equation (3), we find for the current

$$i=2{\cdot}216\,\epsilon^{-237\,t}\sin 1{,}995\,t, \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

the charging E.M.F. being 33·6 volts.

By using equation (1) we find for the potential difference at the condenser terminals

$$v=33{\cdot}6-33{\cdot}83\,\epsilon^{-237\,t}\sin(1{,}995\,t+\alpha), \quad . \quad . \quad (5)$$

where $\alpha=83°\,12'$.

Experiment showed, however, that in spite of the condenser having been short-circuited for a considerable time, its coatings became charged to a potential difference of about 1 volt during the brief period between the instant of open-circuiting it and that of switching on the charging battery. The actual potential difference at the condenser terminals when fully charged was 34·6 volts. Hence the effective charging E.M.F. in the circuit at the commencement of the charge was 33·6 volts, the value used above in calculating the current. In order, therefore, to compare the calculated values of the potential difference with those obtained experimentally, we have to add 1 volt to each ordinate of the curve given by (5). The theoretical curves so obtained are shown in Fig. 2, and the corresponding experimental curves in Fig. 3. It will be seen that there is a very fair agreement between the two sets of curves, such discrepancies as are noticeable being probably due to inaccuracies in setting the Joubert contact (a small displacement of which produced a considerable change in the values of the quantities observed), to variations in the speed of the electromotor driving the switching discs, and to slight errors in taking the electrometer readings.

The curves show very clearly the nature of an oscillatory charge, the oscillations being due to the presence of inductance in the circuit. In another set of experiments, a non-inductive resistance was used. Instead of equation (1), we have in this case

$$r\,i+v=E, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

which by differentiation gives

$$r\frac{di}{dt}+\frac{1}{C}\,i=0. \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Solving this equation, and remembering that when $t=0$, $v=0$, we find

$$i=\frac{E}{r}\,\epsilon^{-\frac{t}{rC}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

The values of the various quantities were as follows:—

$$E=34{\cdot}6\,;\ r=921\,;\ C=32{\cdot}6\times10^{-6}.$$

Substituting in equation (8) we get

$$i=0{\cdot}0376\,\epsilon^{-33{\cdot}3\,t}. \quad . \quad . \quad . \quad . \quad . \quad (9)$$

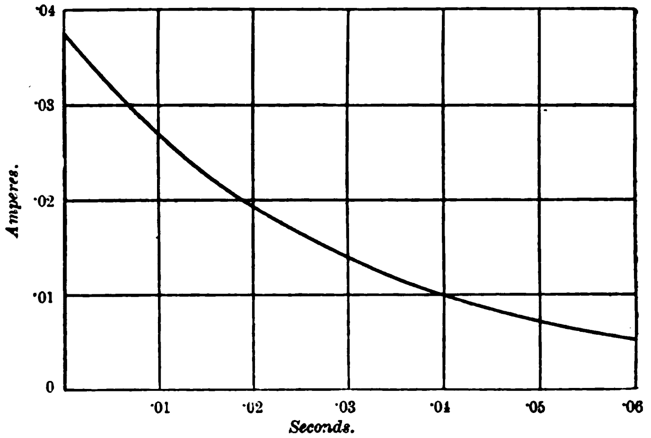

Fig. 4.—Theoretical Curve, Condenser Charged through Non-Inductive Resistance.

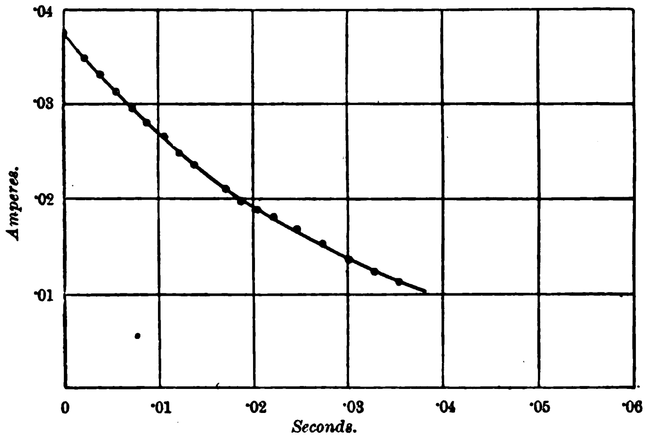

Fig. 5.—Experimental Curve, corresponding to Fig. 4.

The theoretical and experimental curves corresponding to this case are shown in Figs. 4 and 5 respectively. A comparison of the two curves shows that they are in substantial agreement.

The main interest of the above experiments lies not so much in the fact of their showing, qualitatively, the existence of oscillations in the charge, as that they enable us to make a fairly accurate *quantitative* comparison between the actual curves of current and potential difference, and those deduced theoretically.

In conclusion, I wish to thank Mr. G. B. Bryan, a senior student of University College, Nottingham, for assistance in carrying out the experiments.

ALTERNATE-CURRENT ELECTROLYSIS.

BY W. R. COOPER, M.A.

In *The Electrician* for August 23, 1895, some notes were given upon the production of phase-difference by alternate-current electrolysis. My attention has since then been called to a joint Paper by Dr. J. Hopkinson, E. Wilson and F. Lydall, entitled "Alternate-Current Electrolysis," which was read before the Royal Society in 1893. As nothing beyond a note of the work appeared in *The Electrician*, an abstract of the Paper will be of interest, as showing how readily a phase-difference can be obtained when the conditions are suitable—*i.e.*, when the electrodes are close together, and the impressed E.M.F. is not large. This was not, however, the main object of the investigation. The authors desired to determine the efficiency of an electrolytic cell when used as a condenser, and also to gain some idea as to how thick a coating of the ions suffice to give complete polarisation.

In the experiments described, current from a Siemens alternator was passed through two cells in series, having platinum electrodes (exposed on one side only) 23¼ sq. in. (150 sq. cm.) in area placed ⅛in. apart. The current and potential difference at any time were measured by a Kelvin quadrant electrometer,

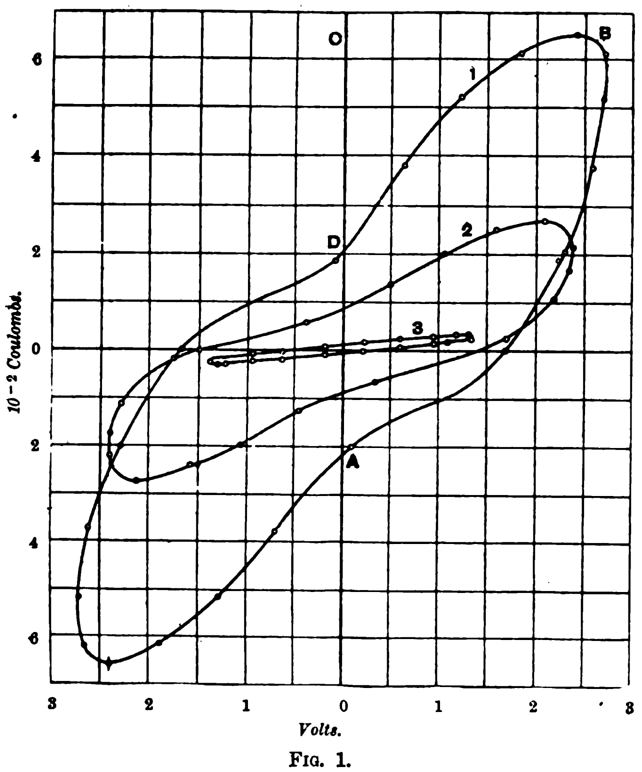

Fig. 1.

in circuit with a revolving contact-maker. The electrolyte used throughout was of water 100 parts by volume and sulphuric acid five parts.

The first part of the Paper deals with the question of efficiency. Curves are given in which amperes and volts are plotted in terms of time. By integrating the current curve, the number of coulombs passing during any desired interval is known; and thence curves are plotted between the potential difference across the cells and the quantity of electricity at corresponding times. These are closed curves after the manner of those due to hysteresis as shown in Fig. 1, and the area of any one of them is a measure of the total energy dissipated per cycle. The efficiency is readily determined. For example, in curve 1 the total energy expended on the cell is proportional to the area A B C, whilst the energy recovered is proportional to D B C. Thus the efficiency of the cell as a condenser is given by the ratio of these areas. Results are given of six experiments in which the efficiency varied from 23 to 43 per cent with the plates ⅛in. apart. In the first case the maximum pressure amounted to 2·7 volts, and the maximum current was 43·3 amperes (curve 1); in the second case the corresponding figures were 1·3 and 2·06 (curve 3).

Experiments are then described in which the frequency was varied as well as the current. The platinum plates were placed ¼in. apart, so that a movable electrode might be intro-

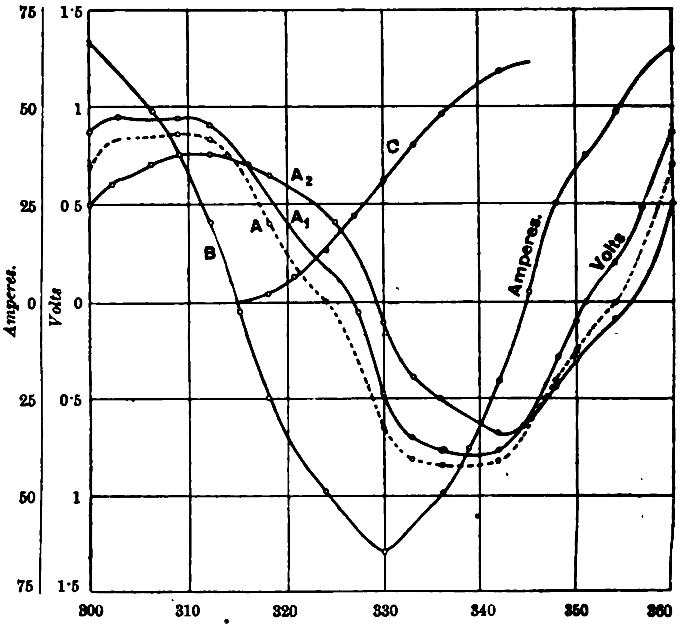

Fig. 2.—Frequency = 142·5 ∿ per sec. Max. Current 65·4 amperes.

duced between them. The potential difference was then measured between one of the plates and the exploring electrode. The curves obtained with a frequency of 142·5 per second are given in Fig. 2, and show a considerable phase

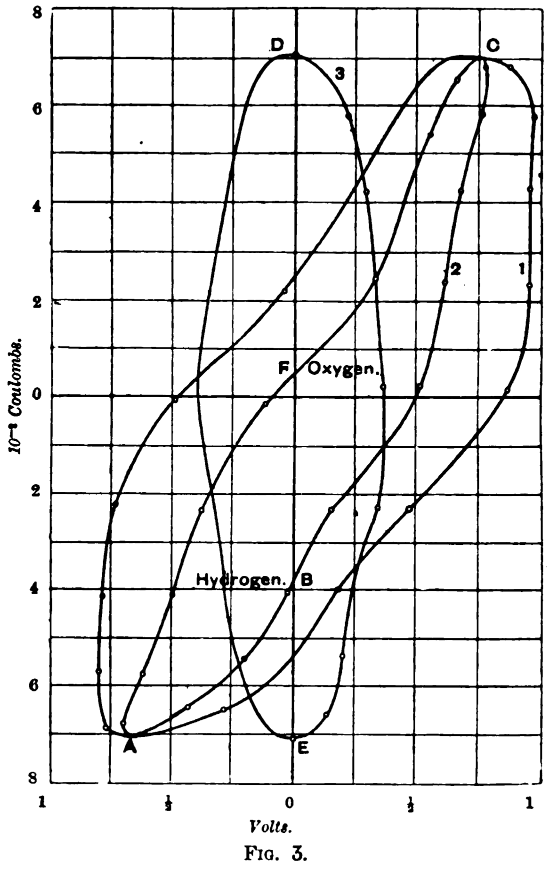

Fig. 3.

difference. The curve A_1 so obtained gives the volts absorbed at any time by the evolution of gas, together with that due to ohmic resistance. From experimental evidence it was estimated that this resistance was approximately 0·0056 ohm. By correcting curve A_1 for this loss of potential difference curve

Digitized by Google

A_2 is obtained and gives the volts at any time absorbed in the decomposition of the electrolyte alone. With this frequency and current the energy dissipated on ohmic resistance is seen to be a large proportion of the total energy dissipated. It will be noticed that the curve A_1 is unsymmetrical, whereas the curve A, giving the potentials across the two platinum plates, is symmetrical.

The curve C in Fig. 2 is the integral of B, and therefore gives the number of coulombs that have passed at any time. On plotting volts as given by curves A_1 and A_2 in terms of coulombs, curves 1 and 2 in Fig. 3 are obtained. The area of the first gives the total energy spent in the cell; that of the second is a measure of the energy dissipated by electrolytic hysteresis.

From observations with a Clark cell it was possible to state which gas was being evolved at the plate during a given half-period. Thus oxygen begins to be directed to the plate at the point A (Fig. 3), as the coulombs are then a maximum, and the current changes sign. But it is being evolved upon a hydrogen plate, and the E.M.F. aids the current as far as the point B. The work done on the plate represented by the area A E B, is therefore negative. At B the hydrogen has been all removed, and from B to C the work represented by B C D is positive. Similarly the area C D F represents work returned by the plate during evolution of hydrogen on an oxygen surface, and the area F A E is a measure of the work done on the plate during the evolution of hydrogen on a hydrogen surface. In this manner the product of volts by coulombs is obtained, corresponding to hydrogen evolved upon an oxygen surface.

The conclusion arrived at is that about one-tenth of a coulomb suffices to fully polarise 150 sq. cm. of platinum, or 0·00000007 gramme of hydrogen is sufficient for 1 sq. cm. of platinum. From which it is inferred that "0·00000007cm. is probably a magnitude comparable with the distance between molecules of hydrogen when this body is compressed to a density comparable with the density of liquids."

SOME POINTS CONNECTED WITH THE PREPARATION OF PURE IRON BY ELECTROLYSIS.*

BY PROF. W. M. HICKS, F.R.S., AND L. T. O'SHEA, B.SC.

We have recently had occasion to prepare for a special investigation considerable quantities of pure iron by electrolysis. Although this has frequently been done before by others, we have not been able to find any published account of the details to be attended to to ensure success. As the process is a tedious one, and cost us much time and trouble to discover the best conditions, it may be useful to put on record some of the difficulties met with and the means adopted to overcome them.

The most complete account of the past attempts to prepare iron by electrolysis is given by Varrentrapp (*D. P. J.*, 187-150), who describes the precipitation of iron from solutions of ferrous sulphate, with or without the addition of ammonium chloride, by means of the current from a single Daniell's cell, using iron wire as the anode.

Lenz (*Jour. für Pr.*, 108-438) adopted Klein's process of using a solution of ferrous and magnesium sulphate carefully neutralised with magnesium carbonate. More recently, Classen, in his book, "Quantitative Analyse durch Electrolyse," describes methods for the electrolytic deposition of iron from solutions of ferrous salts containing a large excess of ammonium oxalate, and also refers to the methods adopted by Rudorf, Brand, and E. F. Smith for the analysis of iron compounds by electrolysis.

As many of the difficulties we met with are not referred to in these publications, we hope that the following notes may be found useful by those who, in the future, require to use this method.

The Solution.

It is generally admitted that the electrolyte should be neutral, and we found it absolutely impossible to prepare coherent masses of iron if the solution contained free acid.

* Paper read before the British Association at Ipswich, Section A.

The electrolyte used was a 5 per cent. solution of crystallised ferrous chloride, to which was added sufficient ammonium chloride to form the double chloride $FeCl_2 2NH_4Cl$. Stronger solutions than this can doubtless be used, but the above strength was adopted as offering the most suitable resistance for the regulation of the current and the fall of potential between the electrodes. The amount of iron salt in solution should, however, not be allowed to get too low, because when nearly all the iron salt is decomposed the solution becomes alkaline from the decomposition of the ammonium salt, and ferrous hydroxide is precipitated by the ammonia thus set free; it may be roughly stated that the amount of iron salt in solution should not fall below from 20 to 30 per cent. of its original strength. To avoid this difficulty, we adopted the plan of daily determining by titration the amount of iron removed from the solution, and adding its equivalent in ferrous chloride. As this was done by siphoning off a certain volume of the electrolyte, an amount of ammonium chloride equal to that removed in the solution was added with the ferrous chloride.

It is very essential that the solution be free from ferric compounds, for their presence seems to lead to the formation of ferric hydroxide, which settles in large quantities at the bottom of the cell, and is often deposited on the cathode, whilst considerable frothing accompanies its formation. It appears, also, that the production of ferric hydroxide ceases as soon as the whole of the ferric compound is decomposed, for in the early stages of our work we were troubled with the formation of this substance whenever we started with a fresh quantity of electrolyte, or added more ferrous chloride to replenish that in use, but after the current had passed for some time ferric hydroxide ceased to form. We effectually overcame this difficulty by shaking the ferrous chloride with reduced iron and filtering just before using. This had the effect of reducing any ferric salt to ferrous before entering the electrolyte. So long as this was done the ferric hydroxide ceased to be deposited on the plate, and the amount which was deposited at the bottom of the cell was small even after working for three weeks.

The Current.

There seems no doubt that, to get the best results, both the terminal volts and the current density must lie within certain limits. This requires regulation by the resistance of the cell itself. The constitution of the electrolyte just given was found to meet the necessities of the case. Classen (*loc. cit.*) gives a density of 0·5 to 1 ampere per 100 sq. cm. for purposes of electrolytic analysis, whilst for steel facing S. P. Thompson ("Dynamo-Electric Machinery") gives 0·5 to 1·5 ampere per 100 sq. in., say 0·08 to 0·25 ampere per 100 sq. cm. We found it was desirable to strike the deposit with a current density of 0·2 ampere per 100 sq. cm., and when the cathode was completely covered to reduce the density to from 0·15 to 0·18 per 100 sq. cm. Although we found it undesirable to exceed these limits, it is possible to considerably reduce the density, and we have used 0·08 ampere per 100 sq. cm. with success.

The current was obtained from a single storage cell, "E.P.S." pattern, having a voltage of 2, in series with a cell of dilute sulphuric acid and lead electrodes. This reduced the voltage to nearly the right value. In some cases we used two depositing cells in parallel without the lead H_2SO_4 cell. A small external resistance then regulated the potential difference between the electrodes to about 0·7 volt.

The Electrodes.

The cathode was a sheet of the thinnest copper procurable, stiffened by mounting on a sheet of glass. In connection with this only two points are of special importance.

Firstly, the well-known necessity of absolute cleanliness. After various trials, the following method was adopted to ensure this. The copper sheet was flushed with nitric acid and water mixed in equal volumes and well rubbed with cotton wool, then thoroughly washed with water and scrubbed with fine sand and excess of a strong potassium cyanide solution. This had the effect of completely removing any copper oxide, and of producing a bright polished surface. Care is necessary

Digitized by Google

that excess of potassium cyanide be used, otherwise a film of copper cyanide may be left on the plate. After well washing with water, the plate was quickly placed in the cell.

The second point is the necessity of completely immersing the cathode in the electrolyte, for the ammonium chloride acts on the copper wherever the latter and the electrolyte come in contact with the air. Copper is dissolved and then deposited on the neighbouring freshly-deposited iron.

To avoid this, and also prevent the deposit from forming anywhere but on the front of the plate, the back and all parts of the front except where the deposit was to form were coated with Brunswick black, so that practically the cathode was wholly immersed in the electrolyte. We previously ascertained that the solution had no action on thoroughly dried Brunswick black.

The anode consisted of rolled Swedish iron, containing 0·029 per cent. sulphur and 0·049 per cent. carbon. As our object was to prepare iron free from these two constituents, we enclosed the anode in a porous cell. The carbon collected at the bottom of this in the form of a black mud, whilst the sulphur passed into solution as sulphuric acid, and it was impossible to avoid some of this passing through the porous cell. This, however, was reduced to an extremely small quantity by changing the solution in the anode cell twice daily, it being replaced from the electrolyte, withdrawn as before explained from the cathode cell, and diluted so as to contain 1 per cent. ferrous chloride. This enabled us to obtain the iron quite free from sulphur.

By taking these precautions a firmly coherent deposit of iron was obtained which presented a surface of almost silver whiteness and of a somewhat velvety appearance, but, as Varrentrapp and Lenz point out, it contained numerous small holes of a conical shape. These are doubtless due to the formation at starting of small microscopic bubbles which prevent the iron from being deposited. The bubbles appear to grow with time, so that unless cleared away the area of iron shielded by them increases and a conical pit is produced. As the surface of iron under them is quite dry and they are partially shielded by the hole itself, it is very difficult to clear them away by rubbing. It was attempted to do this by means of an automatic scraper, which passed every 15 minutes over the surface of the plate, but it was not completely successful. It will probably be better to have an automatic arrangement whereby the cathode is raised bodily out of the electrolyte and exposed to the air for a few seconds, when the bubbles will break of themselves.

When the apparatus was in working order the iron was deposited at the rate of about 3 grams per 100 sq. cm. in 24 hours.

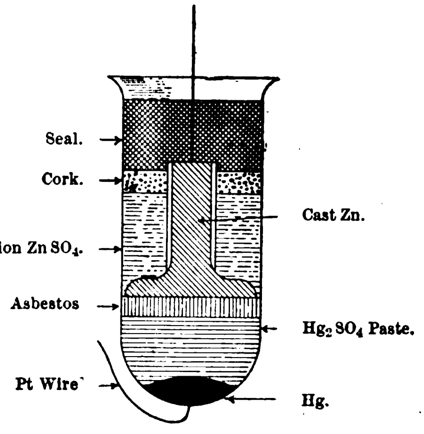
With the above precautions the process worked continuously and without interruption.

A PORTABLE CLARK CELL.*

BY HENRY S. CARHART.

The form of Clark cell adopted as a legal standard by Act of Congress is the modified H form, designed by Dr. Kahle, of Berlin. This form as a primary standard I recommended to the committee of the National Academy of Science as preferable to the one adopted by the English committee, chiefly for the reasons that it contains no foreign material—such as cork—to affect the E.M.F., and a saturated solution of zinc sulphate is always in contact with the zinc amalgam. In the English test-tube cell the zinc rod dips down into the solution, and its upper portion is often in a less dense solution than the other end. That this is so I have demonstrated by letting such cells stand for long periods, and in every case zinc has been removed from the rod near the surface of the solution and transferred to the lower end, where it was deposited as a ring or enlargement.

I have found it possible to so modify the test-tube form as to make the cell portable and still free from the above objection. The materials correspond precisely with the legal requirements. The cell is illustrated in the cut. The zinc is cast with a foot which nearly fits the tube, and this foot holds down the purified asbestos so as to prevent the displacement of the mercury and the mercurous sulphate during transportation. Only a single thin slip of cork is used, and this is specially prepared and finely boiled in paraffin. The zinc stem is turned down so as to leave the foot as a flat plate. The stem is then covered with a glass tube, cemented to it by a non-conducting wax. Fine crystals of zinc sulphate are mixed with the mercury salt, and more are placed on top of the zinc plate. Thus the zinc is in contact with liquid only at the bottom of the solution and in the presence of the crystals.



This cell is rather troublesome to set up, but with proper care and skill a cell can be made which has none of the objections of the English form, except the presence of the cork, and moreover it is portable. One of these cells was compared with one made in accordance with the legal instructions, and the relative E.M.F.'s were represented by the following numbers:—

Legal form..9,808·3
Portable form ....9,808·6

Even this minute difference, which can hardly be measured with accuracy, may have been due to a slight difference of temperature, or to the well-known lag of the E.M.F. behind temperature changes.

AN ELECTRIC JIB CRANE.

The accompanying illustration shows an electric jib crane, made and used by the Sandycroft Foundry and Engine Works Company at its works at Sandycroft, Chester. The illustration shows the crane in the act of lifting from a railway wagon a billet of steel, weighing one ton, to deposit it near one of the furnaces. The billet, it seems, is destined to be heated for forging into the "Sandycroft" shoes and dies. This handy lifting apparatus was made by the Sandycroft Company under patents granted to Dr. N. S. Keith.

A 3 H.P. bi-polar motor is geared to the winding drum through an electromagnetic clutch on the lowest wheel disc, and may run continuously. When lifting, the clutch is brought into engagement by the movement of an electric switch at the operator's left hand. When lowering the load the switch is opened; the clutch then disengages, and the operation is controlled by the brake, the handle of which is shown in the operator's right hand. By another switch on the same switchboard another electromagnetic clutch is thrown into engagement with suitable gearing connected with the motor, for slewing the load to the right or left.

The electro-magnet at the billet on the end of the chain weighs 300lb., and takes $5\frac{1}{2}$ amperes at 110 volts to excite it to its working magnetisation, when it will lift a weight of iron or steel exceeding two tons. This electro-magnet is controlled through a switch on the switchboard, or else through one con-

* From the *Electrical World*. The cut shown by our contemporary did not exactly correspond with the description, as was pointed out by Prof. Carhart. We have therefore taken the liberty of re-drawing the cell to fit the description given.

indeed reply that since the profits are of electrical origin, preference should rightly be given to electrical methods. But let that pass. We need only point to unimpeachable figures obtained from actual experience to justify our assertion that for the economical, æsthetic and effective lighting of main streets, big squares and open spaces, the arc light has no equal. And even for side streets gas will find itself hard pressed wherever municipalities supply their own current, unless the durability of the incandescent mantle, when exposed to the vicissitudes of an outdoor life, is markedly increased.

The need for more light out of doors which is genuinely felt by the general public does not arise merely from the vast vehicular and pedestrian traffic which takes place nowadays after dark, but is due also, as M. Blondel points out in an article which will be found in another column, to the fact that every advance in private lighting inevitably involves a corresponding improvement in public lighting. The two progress *pari passu*, and as M. Blondel assures us that "our requirements will not be *absolutely* satisfied until artificial lighting becomes equivalent to that of the average daylight," the prospect for ratepayers and for borough surveyors is somewhat alarming. Decidedly better street lighting, however, is undoubtedly the need of the hour; even the St. James's Vestry, which rejoices in the distinction of having within its jurisdiction some of the worst-lit streets in London (and that means much), is bestirring itself, and is—will it be believed?—contemplating the erection of no less than 69 arc lamps. Under these circumstances, it is very desirable that those responsible should not only inform themselves as to what has been done elsewhere, but should master the scientific and theoretical aspect of the question. The essential simplicity of the problem has, indeed, been not a little obscured by a fine display of mathematics, and a handbook on the art of public lighting couched in lucid language and avoiding unnecessary elaboration is much wanted. Pending the advent of some such manual, lighting engineers cannot, perhaps, do better than digest the contents of a Paper on "The Distribution and Measurement of Illumination," read before the Institution of Civil Engineers in May, 1892, by Mr. Trotter, and the contents of his Paper read recently before the British Association at Ipswich are also greatly to the point. Of course, we are all aware that the number of inconstant and incalculable factors in street lighting problems render the predetermination of an illumination "characteristic" anything but a triumph of scientific foresight. Nevertheless, a study of the goal to be aimed at, and an examination of the theoretically best way of attaining it, will not be mere waste of time. Indeed, the pressing question—at any rate for those who are to pay the piper—is whether public arc lighting is to be *improved* or *extended*. Is the money to be spent merely in augmenting the number of lamps in streets already electrically lighted, and in extending the blessings of the arc to streets which have not hitherto experienced them; or is the same sum to be laid out to a better advantage by a more intelligent appreciation of the problem in hand and a bolder use of available optical appliances?

And what is the goal to be aimed at? At one time many were led astray by that Will-o'-the-wisp—uniform illumination. To give a street uniform illumination is not, indeed, beyond the resources of science, but it is decidedly beyond the resources of the ratepayers, unless, of course, the lighting is to be uniformly poor. Then, again, others appear to have contented themselves with merely intensifying the old "pilot-light" system; the boundaries between pavements and carriage ways are defined by lines of lamps, and distribution is neglected altogether. At one end of the scale we have an unattainable ideal—if ideal it be, which is extremely doubtful—at the other end we have a disgraceful ideal. Is there no happy mean, and if there is, is it worth a little trouble and study and experiment to attain? One evening last summer we took an evening stroll and soon found ourselves stepping from the dimly lighted though by no means religiously gas-lighted side streets, into a broad main thoroughfare illuminated by 14 ampere arcs under large ground-glass globes. The contrast between the two methods was most striking. Having nothing more pressing to do, we amused ourselves by trying to analyse our sensations; why was there such a warmth and such an exhilarating effect? The outcome of our cogitations was that our pleasurable feelings were not due to a good dinner, for we had not dined, nor to a fat balance at the bank, but to the beautifully adjusted luminous maxima and minima—the former not too painfully brilliant, the latter not too painfully dark—and to the existence of an appreciable amount of diffused light. It is satisfactory, therefore, to learn on M. Blondel's authority that "The public is indifferent as to the uniformity of illumination. They wish to have a street not only moderately well lighted as a whole, but also to have some places more brilliantly illuminated." Towards the attainment of this end a little scientific consideration of the general problem would be helpful. Alas! the science that exists is somewhat too abstruse for that much over-tasked biped—the borough surveyor.

But what, it may be objected, is the use of making all this pother about such an unremunerative job as public lighting? There is, however, a healthy maxim to the effect that what is worth doing is worth doing well. And, although jobs which have to be done at cost price or less cannot be recommended to dividend-earning concerns, street lighting contracts are occasionally entered into by companies to propitiate the parochial powers that be, or as an outward and visible electric sign of considerable advertising value. In either case the job were preferably done well than ill. And by well, we do not merely mean lavishly, but scientifically, economically, creditably. The greater part of our public arc lighting is, however, destined to be done at its cost price by municipalities. Here considerations of the public purse and the public advantage should be paramount, and surely no municipal engineer worth his salt will rest content to do as others have done before him, and argue that he has done all that is required of him merely because the total candle-power now runs into millions instead of thousands.

REVIEW.

Alternating Electric Currents. By E. J. Houston, Ph.D., and A. E. Kennelly, D.Sc. (New York: The W. J. Johnston Company. 1895.)

This little book is the first of a projected series of small elementary treatises intended to deal in a non-mathematical and plain-spoken manner with various subjects of practical electrical interest. It is refreshing to find that these distinguished authors, Drs. Houston and Kennelly, have written a whole book without feeling it necessary to use a single mathematical formula; and our pleasure at this was enhanced when we found that, even with this limitation, they had succeeded in conveying, in an intelligible and interesting way, the main facts about alternate-current machinery. The book is intended for a certain class of reader—the non-technical man; and the style adopted by the authors is eminently adapted to reach that class. The explanations in the text are assisted by a number of neat illustrations and diagrams. The book is neatly and strongly bound.

GAS ENGINE ELECTRIC SUPPLY STATIONS.—IV.*

Coatbridge.

The gas engine electric supply station of the Scottish House-to-House Electricity Company, at Coatbridge, near Glasgow, was inaugurated at the end of March, 1894. It was the second station of this type to be put in operation in the United Kingdom; and in many respects its design and construction were a great improvement upon the Morecambe station. On the other hand, owing to the differences between the electrical systems adopted in these two stations, difficulties and troubles arose in the later one which have been absent from the earlier. We have seen that at Morecambe a continuous-current system, with electrical storage, is in use, and it has been shown how the presence of the storage plant has influenced the running of the engines. At Coatbridge, not only could no electrical storage be used, owing to the fact that an alternate-current system had been adopted, but the gas engines were not even permitted to run independently of one another. They were, so to say, tied hand and foot, yoked together by the irksome necessity of running their alternators in parallel. These facts may afford some explanation of the decision of the Scottish House-to-House Electricity Company, in the early part of this year, to abandon gas plant, and to run their station by steam power.

Notwithstanding this important change, which places Coatbridge outside the category of gas engine stations, it will be instructive briefly to study the construction of the station at the time of its inauguration. A view of the interior of the engine room is shown in Fig. 1. This room forms part of a substantial stone structure adjacent to the North British Railway; and is situated in a district which abounds in iron and steel works, noisome odours, and an exemption from the usual laws as to nuisance from smoke and smell. Here carbon monoxide or water gas may hold almost undisputed sway—disputed only, at any rate, by the sulphureous odours from the blast furnace and the slag pit. The scale plan of the buildings, in Fig. 2, shows the general arrangement and size of the several rooms, &c.; but it should be remarked that the offices, store and testing rooms, &c., which lie to the left of the engine room, have been omitted. Adjoining the engine room is an almost detached building, which contains the gas generating plant; and beyond this are the gas coolers, scrubbers and holder.

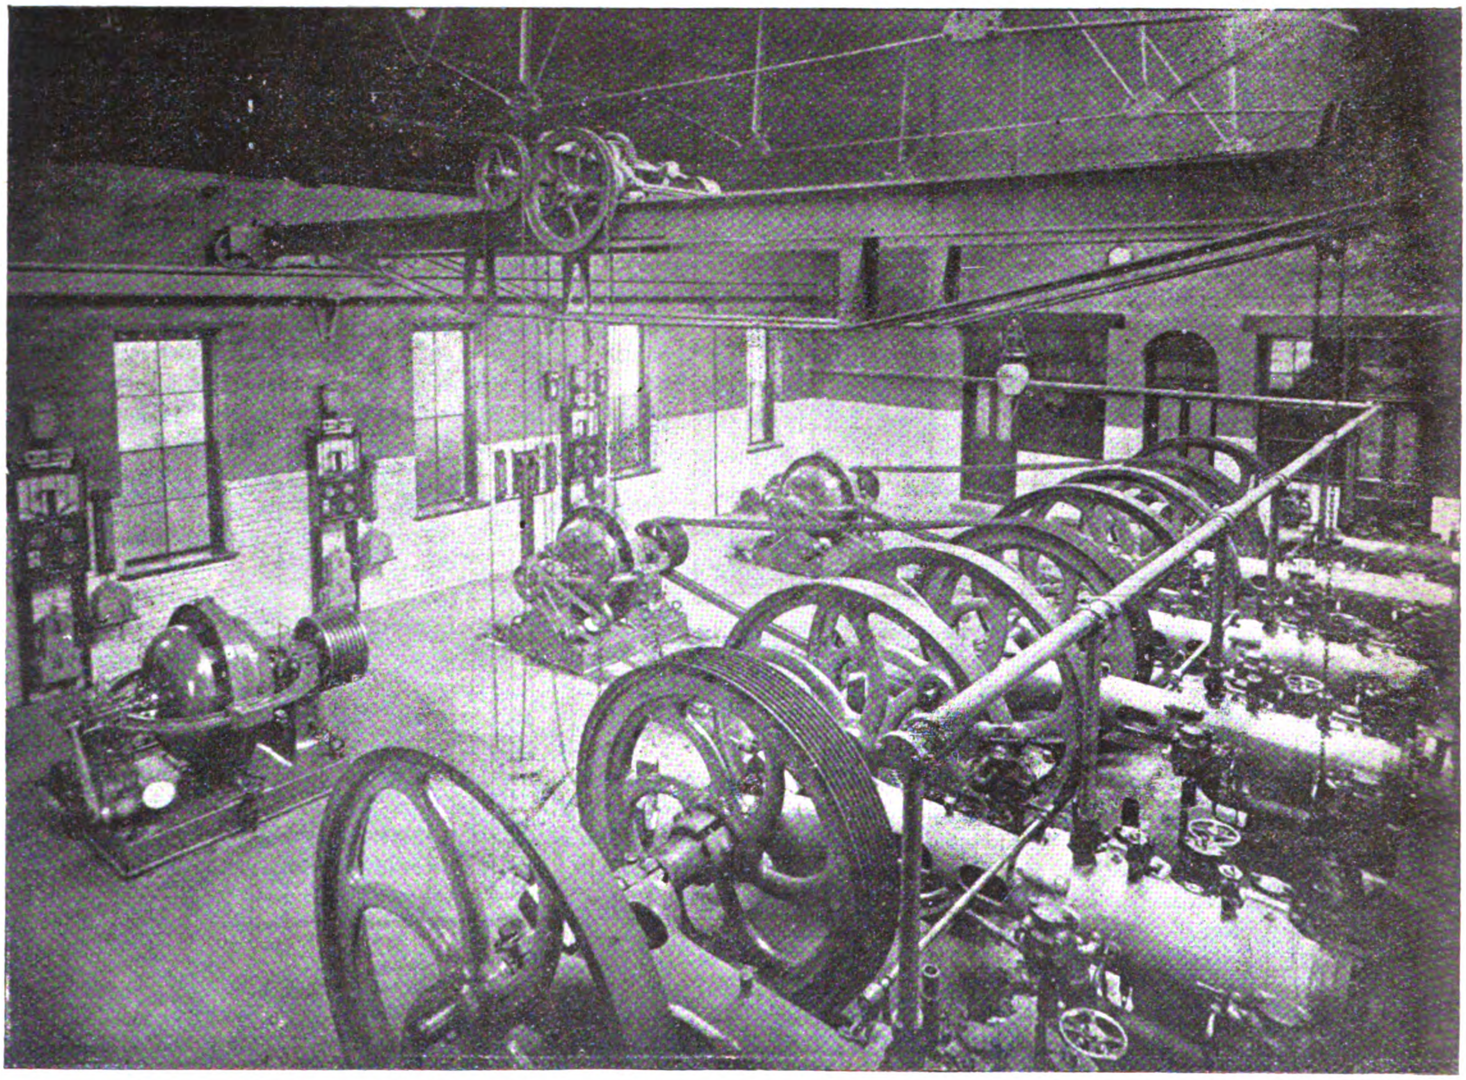

Fig. 1.—Coatbridge Gas Engine Electric Supply Station. Interior of Engine Room.

There are two gas producers, each capable of generating gas for about 120 B.H.P. These are a modification of the Dowson gas producer, and are fitted with an apparatus for conveniently removing clinkers, invented by Mr. J. W. Hartley. A transverse section of the plant is shown in Fig. 3. Anthracite is used in the producer furnace and is subjected at white heat to a blast of air and superheated steam. The gas produced is of the same composition as Dowson gas. After passing through the cast-iron cooling stack and the hydraulic dust-box, the gas is scrubbed in the coke scrubber and filtered through sawdust. It then passes into the gas holder. Steam is generated in two small vertical boilers, which are fired with coke. The steam is used both for the generator blasts and

Digitized by Google

occasionally for starting the gas engines. The gas plant is so arranged as to minimise the cost of conveying the fuel from the railway to the furnaces. The fuel may be loaded direct from the truck on to the charging platform, and the level of the gas producers is lowered into a pit, so that the bell-mouths are at a convenient elevation for receiving the charges of anthracite. The gas holder is 15ft. in diameter and is 10ft. deep.

In the engine room there are three sets of gas engines, driving alternators by means of cotton ropes. The gas engines are of the double-acting, two-cylinder, side-by-side "Kilmarnock" type, and were built by Messrs. Dick, Kerr and Co., by whom the whole of the gas plant was supplied. The engines work on the "Otto" cycle, and run at a speed of 180 revolutions per minute, each complete engine developing 120 I.H.P. The engines are controlled by high-speed "Buss" governors, which reduce the quantity of the explosive charge down to one-third of full power, and at lower powers cause some of the explosions to be missed. At full power there are two explosions during every revolution of the engine. In order to minimise the fluctuation of speed, each engine was provided with three heavy flywheels; the middle wheel being grooved for a rope drive of eight 1in. ropes. Mordey alternators, constructed by the Brush Electrical Engineering Company, are driven at 600 revolutions per minute, developing a normal output of 50 kilowatts each. In order to start the gas engines a steam starter is used, the construction of which is shown in Fig. 4. A steam pipe runs along the side of the engine room, behind the engines, and a branch pipe communicates with the steam starter on each engine. The starter comprises a steam chamber, communicating with the compression chamber of the engine cylinder, the connecting passage being opened or closed by a valve actuated by a hand lever. The engine is first brought on to an early part of the forward stroke, with the starting valve closed. Opening now this valve will give a forward stroke of sufficient energy to bring the crank once round, the starting valve being promptly closed at the end of the forward stroke. A succession of well-timed impulses produced in this way will soon get the engine up to speed, when the gas and air and ignition valves may be put into action; and no doubt the condensed steam soon disappears from inside the cylinder.

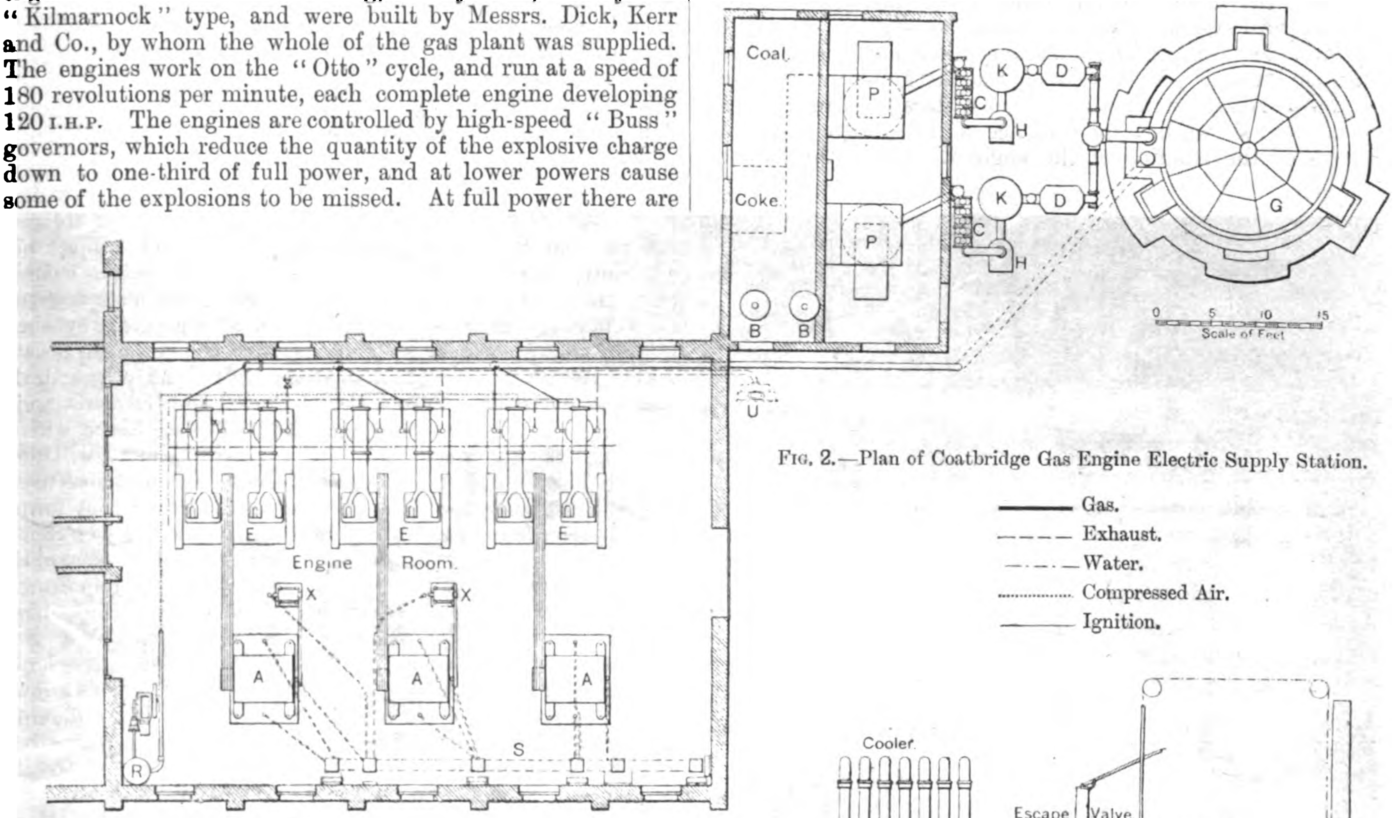

FIG. 2.—Plan of Coatbridge Gas Engine Electric Supply Station.

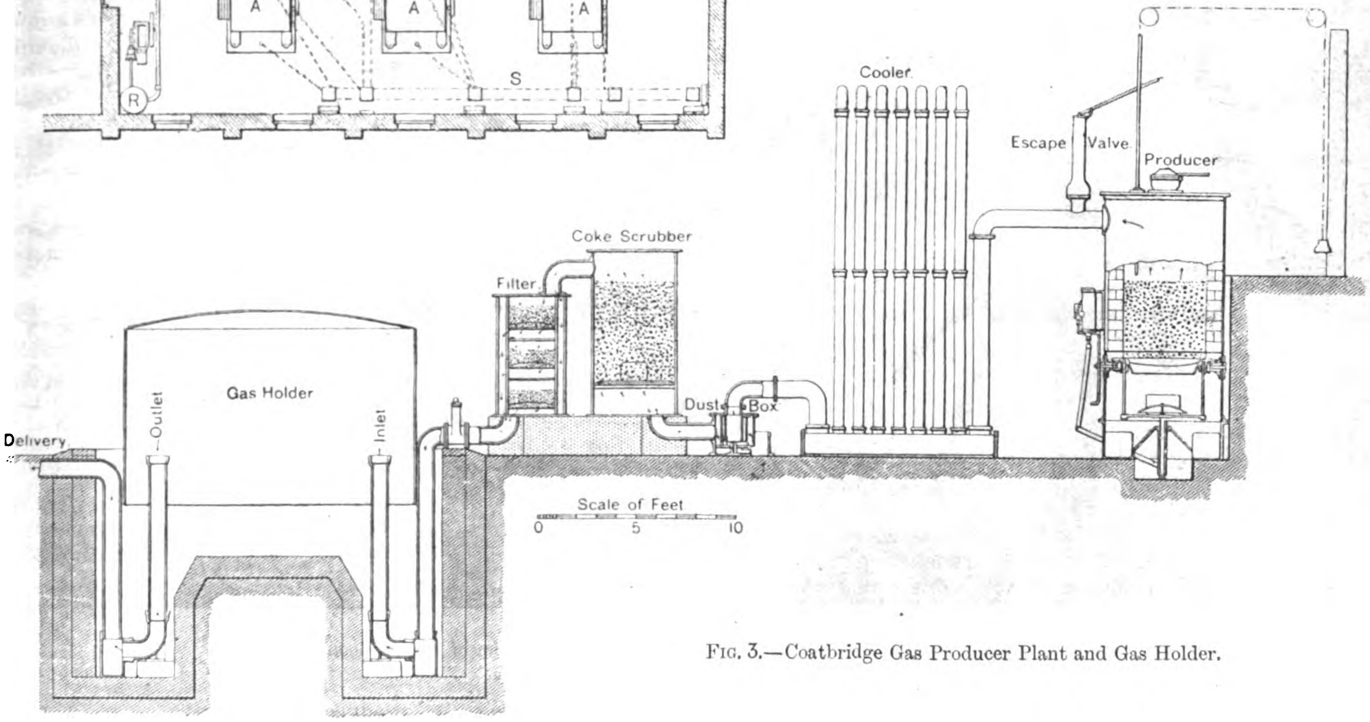

FIG. 3.—Coatbridge Gas Producer Plant and Gas Holder.

In conclusion, we may note one or two details as to the cost of running the Coatbridge gas engine station. The first item of expense, the anthracite, costs 12s. 6d. per ton; and at this price the average cost of fuel per unit sold is from 0·6 to 0·7 penny. Sawdust for renewal of the scrubbers costs 2s. 6d. per week. Ignition tubes have been a serious item; each tube lasting only one day, four tubes being required on each engine at the same time, and each tube—of wrought iron—costing 3d. Thus the item of ignition tubes has

Digitized by Google

amounted to 1s. per diem per engine, or £1. 1s. per week for the entire station. Ignition tubes, however, can do better than this! Oil, too, has been an item the cost of which cannot be ignored. About ¾ gallon per engine per diem is consumed and, not being filtered, is not re-used. The cost of this item is therefore about £1. 12s. per week for the entire station. For steam raising, about 2½ tons of coke are consumed per week. The quarterly output of the station, at the time about which we are writing, may be taken at about 12,000 Board of Trade units. The price charged for the supply of energy to customers is 5d. per unit.

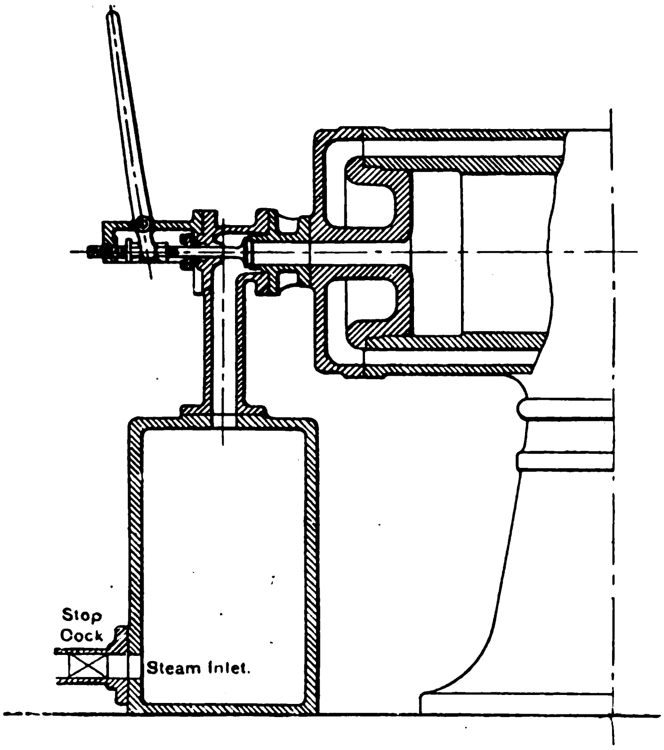

Fig. 4.—Steam Starter for Gas Engines at Coatbridge.

We are indebted to Mr. Francis Teague, the resident engineer at Coatbridge, for much of the information published in this article; and to the Scottish House-to-House Electricity Company and Messrs. Dick, Kerr and Co., for permission to publish the illustrations which accompany it.

MAGNETIC UNITS.*

The question of magnetic units may be said to present three issues—one relating to the need of specific names, another to the magnitude of practical units, and a third to the selection of names. In regard to the first, our English contemporary, *The Electrician*, which had always expressed itself in opposition to specific names for magnetic units, in summing up a recent and extensive correspondence on the subject in its columns, frankly admitted a strong drift of opinion favouring such names. It is gratifying that the soundness of the American view has thus been confirmed, and still more so that the British Association has added its formal approval. As to the action of the British body on the second issue, we believe a grave mistake has been made in creating a new unit. In their reports on the International Congress proposals of the American Institute of Electrical Engineers, the national electrical associations of both France and Germany officially arrayed themselves strongly against the making of new magnetic units and in favour of the C.G.S. system for practical use, and the national American body has definitely committed itself to the same position. The British Association, therefore, can scarcely hope in view of this to ever see its unit of magnetic flux enter into international use, and consequently its creation is little less than a misfortune to the British electrical profession, and a menace to international scientific unity. As to the names adopted, did we not have the highest respect for the British Association we might have difficulty in escaping from the thought that its action lacked international courtesy. The American system of units was thoroughly discussed before its committee, and it must have been known that it had already entered extensively in use in this country; in the light of this it was certainly inconsiderate to appropriate the names here adopted and apply them in an entirely different manner in another system. In one case the name of the C.G.S. unit of magnetic flux is applied to a new unit of the same quantity, and in another the name of the C.G.S. unit of magnetic intensity to the C.G.S. unit of M.M.F. As the B.A. system, like the American system, is merely proposed as a provisional one subject to international approval, it would have been infinitely better to have either adopted the gilbert in one case, or, as should have been done in the case of the unit of flux, used another name. To sum up, as the matter now stands, there are two sets of practical magnetic units before the world on trial previous to final international action on the subject of such units, which action will probably not be taken before 1900. Of the two sets, the American forms a complete system and is already in extensive use; it was originated by the British Association itself 20 years ago, and therefore can boast in this respect the sanction of that body. As a practical system it meets the approval of the French and Germans, and there is every reason to believe that they, five years hence, when the names shall have become firmly fixed in this country, will not seriously object to their definite adoption for international use. On the other hand, the B.A. units are inconsistent; they form an incomplete system and one which cannot practically be completed; by including a new unit, determined continental opposition is actually invited; and, perhaps most important of all, the student, whose needs are most concerned, has another burden added instead of being relieved. We are inclined to believe that if the British Association, instead of attempting to settle a question of extreme importance in a few hours, had put it over to another meeting, quite a different result would have been attained. As it is, there seems to be no hope of its proposals finding acceptance outside of Great Britain, and it remains to be seen if they even secure support there. Should they, however, finally secure favourable action from an international electrical congress, Americans can only say, "Very well, gentlemen, if you all decide to adopt new 'practical' units which we don't think we want, as we work very comfortably without them, we will, nevertheless, adopt them in the interest of international unity; we only filled in the dreary waste that existed by giving temporary names to C.G.S. units."

It is to be sincerely regretted that the British Association, which in the past has done such excellent work for the advancement of electrical engineering, has just promulgated two proposals for practical magnetic units which are inconsistent, burdensome and equivocal. It is a matter for congratulation that the British Association has recognised the existing necessity among electrical engineers of adopting specific names for magnetic units. It is to be regretted that they cannot be congratulated upon their selection of such names. It is very doubtful if these practical units and names will meet with general adoption, on account of the grave objections which may be urged against them.

The most important objections are perhaps the following:—

1. The units are inconsistent. The suggested unit of flux belongs to the practical system of the ohm, volt, ampere, coulomb, joule and watt, while the suggested unit of M.M.F. belongs to the C.G.S. system. The practical system is virtually based on the earth-quadrant, the 10^{-11} gramme, and the second, while the C.G.S. system is based on the centimetre, gramme and second. Consequently, none of the equations relating to the magnetic circuit, such as $\Phi = \frac{F}{R}$, can be carried out with these two units, unless factors are introduced which are difficult to remember.

2. The units are incomplete. If units for the four quantities—flux, M.M.F., intensity and reluctance—had all received either "practical" or C.G.S. values, and had been so christened by the British Association, at least a complete and comprehensive system would have been created. As it is, with the two hybrid units offered, it is necessary for the student to first make himself acquainted with the C.G.S. system in learning the fundamental relations of the magnetic circuit, and then to learn the new "practical" unit value of magnetic flux. The labours of the student, instead of being lightened, are thus needlessly increased by the proposed change. Again, if in the future it should be desired to complete the magnetic system by the addition of a practical unit of reluctance, this

* From the *Electrical World*, October 5, 1895.

Digitized by Google

unit will have a value of one hundred millionth of the C.G.S. unit, and the reluctances of usual dynamo circuits will be of the order of hundred of billionths (10^{-11}).

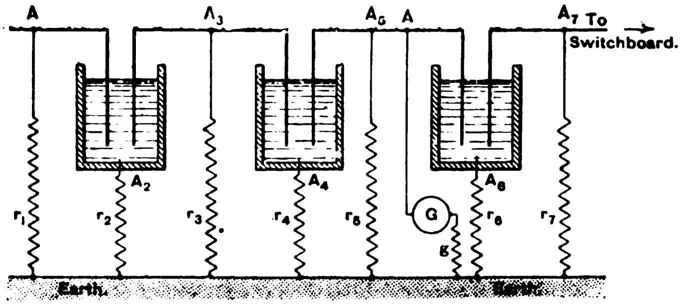
3. The names proposed for the units are equivocal. If the Committee of the British Association could not see fit to accept the units provisionally adopted by the American Institute of Electrical Engineers, it would at least have been conducive to the interest of electrical engineering to suggest names that were not already extensively used with entirely different meanings. The serious objection is that they have selected the name weber for a unit of magnetic flux one hundred million times greater than the American unit of the same name. They have also selected the American unit of M.M.F., here called the gilbert, and have proposed to name it the gauss, which is the name for the American Institute unit of flux density. Assuming that the British Association will use these new names, the perplexity of a student in finding two webers of different values and two gausses with entirely different meanings can best be imagined.

If the new British Association system of magnetic units possessed even the merit of consistency and completeness, there might be some hope of its adoption in America, if only for the true interests of engineering progress, but the American Institute system, being a consistent and complete system—namely, the C.G.S. system, which has been in international use for the last 20 years, and originally created by the British Association, it cannot be expected that it should be replaced by the incomplete hybrid system proposed.

A SIMPLE METHOD OF MEASURING THE INSULATION RESISTANCE OF STORAGE BATTERIES.

BY E. S. JACOB.

The insulation resistance of dynamos, leads, &c., is easily measured when no current is flowing; it is ordinarily obtained with the Wheatstone's bridge, the ohmmeter, or, more roughly, with a high-resistance galvanometer, calibrated with a given number of cells in circuit. In the case of a storage battery, however, owing to the different E.M.F. existing in the circuit, as soon as the cells are filled with acid, none of these methods can be used; on the other hand, the resistance measured before filling has absolutely no value for practical purposes. If the earths were equally distributed over the battery, it would be possible to get some result by means of a high-resistance galvanometer alone; but this is rarely the case, and apart from the fact that the earths are of unequal resistance, they are sometimes due to the containing vessels, of which the potential is rather uncertain, and sometimes to the leads which connect the battery to the switchboard. The following simple method obviates these difficulties, and gives immediately the joint resistance of all the earths at whatever points of the battery they may be situated.



Connect any point of the battery through a sensitive high-resistance galvanometer to earth; the deflection will be a minimum at a certain point of the battery, and will gradually increase on receding from it in either direction; the point chosen should give a large deflection on the galvanometer scale. Now, keeping the connections as before, insert in the galvanometer circuit a resistance such that its deflection may be reduced to, say, about one-half of its former value. Then, if

c be the current through the galvanometer in the first case;
c^1 be the current through the galvanometer in the second case;
g be the resistance of the galvanometer circuit in the first case;
g^1 be the resistance of the galvanometer circuit in the second case; and
R be the insulation resistance of the battery,

$$R = \frac{c^1 g^1 - c g}{c - c^1}.$$

Let $A_1\,A_2\,A_3 \ldots$ &c., be points of the battery (containing vessels, or leads) connected to the earth;
$r_1\,r_2\,r_3 \ldots$ &c., be the resistances between the points $A_1\,A_2\,A_3 \ldots$ and the earth;
$c_1\,c_2\,c_3 \ldots$ &c., be the currents flowing from $A_1\,A_2\,A_3 \ldots$ to the earth, when the galvanometer is connected;
$E_1\,E_2\,E_3 \ldots$ &c., be the E.M.F. between the point A (where the galvanometer is connected to the battery) and the points $A_1\,A_2\,A_3 \ldots$

Let all the currents be supposed to flow from the battery to earth; then

$$c_1 r_1 - c g = E_1,$$
$$c_2 r_2 - c g = E_2, \text{ \&c.}$$
$$c g - c_6 r_6 = E_6,$$
$$c g - c_7 r_7 = E_7, \text{ \&c.,}$$

and $$c_1 + c_2 + c_3 + \ldots + c = 0.$$

Hence $$\frac{E_1 + cg}{r_1} + \frac{E_2 + cg}{r_2} + \ldots + \frac{cg - E_6}{r_6} + \frac{cg - E_7}{r_7} + \ldots + c = 0$$

When the resistance of the galvanometer circuit becomes g^1, c become c^1.

Then, in the same way as above, we have

$$\frac{E_1 + c^1 g^1}{r_1} + \frac{E_2 + c^1 g^1}{r_2} + \ldots + \frac{c^1 g^1 - E_6}{r_6} + \frac{c^1 g^1 - E_7}{r_7} + c^1 = 0.$$

Subtracting the second equation from the first,

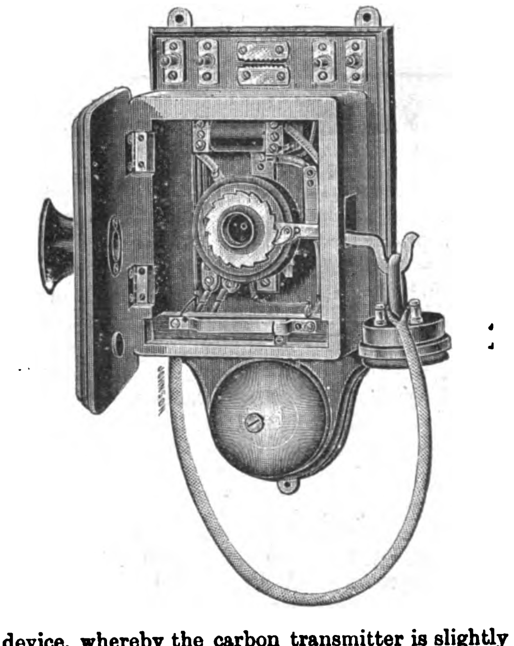
$$(cg - c^1 g^1)\left(\frac{1}{r_1} + \frac{1}{r_2} + \ldots\right) + c - c^1 = 0,$$

or $$R = \frac{cg - c^1 g^1}{c^1 - c}.$$

All the apparatus used in this method is such as forms part of a set of ordinary testing instruments, and the results are true under every condition; the same method might be used for measuring the insulation of a complicated network, *e.g.*, a five-wire distribution, while current is passing.

AUTOMATIC REVOLVING TELEPHONE TRANSMITTER.

Owing to the liability of some types of carbon-granule telephone transmitters to occasionally get out of order, through the settling of the carbon into a compact mass, Messrs. Gent and Co. have intro-



duced a device, whereby the carbon transmitter is slightly rotated on its axis each time it is used. The accompanying illustration shows one of their automatic revolving transmitters, so arranged that the rotation shall be effected by the switch hook. The lever of the hook actuates a pawl and ratchet motion on the transmitter. In a later form of the apparatus the rotation is effected by the ringing key.

ELECTROLYTIC COPPER-REFINING IN NORTH AMERICA.*

BY E. SEDERHOLM.

In America they do not electrolyse ores and matters direct, only converter copper with 98 to 99·3 per cent. and blister copper with 99·5 per cent. of Cu being thus treated. Pitched wood is employed in the construction of the vats, and they are lined with lead, which is in the end more satisfactory, as is done in the new works in Salt Lake City, or they are used without such lining, as at Great Falls, in the works of the Boston and Montana Copper and Silver Mining Company. There is a space of from 30cm. to 60cm. between the lowest portions of the electrodes and the bottom of the vat, to allow for the accumulation of slime and solid matter ; and a cock is provided for the withdrawal of the slime into a channel, communicating with all the vats, and leading to a single reservoir. Along each side of the vat runs a square copper rod, one rod forming the positive, the other the negative lead, the anodes being so suspended that the supports rest on one of these rods at one end, but are insulated from the other rod by means of a strip of wood. The cathodes are similarly but conversely connected and insulated. A pipe placed above the vats admits the fresh solution, and each vat has an overflow pipe connected with a common reservoir. The solution is here brought up to the right acid strength ; or if very impure the copper is extracted electrolytically or by means of iron, refined, and cast into anode plates again. The Chicago Copper Refining Company crystallise out the copper sulphate, and separate the arsenious oxide by re-crystallisation. There is a good market for both products.

The dynamos are of all possible types, the voltage depending upon the number of baths in series. In the larger works the machines are generally separately excited. The voltage of the older machines was from 6 to 30 volts, but now the terminal voltage ranges from 100 to 200. At the Great Falls installation four Thomson-Houston four-poled dynamos, excited by two smaller machines, are used, and each generator gives a current of 1,000 amperes and 200 volts, the number of baths in operation being 288. As it is important that the voltage should not be too high when the solutions are impure, the difference of potential in the baths is controlled by altering the space between the electrodes. The current varies from 70 to 150 amperes, which is much higher than that recommended in Europe.

In America the systems of Smith, Stalman and Hayden are used; the first (English patent 17,340, 1888) in one works only and the latter (English patent 2,071, 1888) in many. In all of them the electrodes are placed in series, and (with some modifications) each plate serves both as cathode to the preceding plate and as anode to that which follows until the original plate has been completely replaced. In Smith's process they are arranged horizontally, cotton cloth stretched between each layer separating the plates, the top plate forming the anode. In the older multiple system the anodes are cast direct from the reverberatory furnace or converter into plates 2·5mm. to 3mm. thick. By running from the converter, as proposed by Thofern, labour is saved, but the metal is less homogeneous ; and being unequally attacked in the vats it tends to break up, so that large fragments of copper may fall with the slime to the bottom of the bath, which seriously interferes with the economical working of the process. The cathodes are usually thin sheets of electro-deposited (not rolled) copper, and the process is ultimately allowed to proceed until they are 8mm. to 12mm. thick. The solution generally contains initially 150 to 200 grammes of crystallised copper sulphate and 50 grammes of sulphuric acid per litre, and must be kept up to this strength throughout. For very large currents a stronger solution is employed. In practice the electrodes are removed every second day, the anodes being cleansed from slime and the cathodes being freed from projections. Both are then returned, unless the former are dangerously thin, when they are re-cast.

Many different methods have been proposed of treating the anode slime. Hot, strong sulphuric acid has been employed, and this dissolves most of the silver, which is then precipitated by granulated copper ; but the acid is wasted by this process. The silver obtained is fairly pure (99·5). The undissolved silver is in combination with selenic and antimonic acids, and is accompanied with some gold. Ulke dissolves out the whole of the copper by means of warm dilute sulphuric acid, through which air is blown, leaving a residue which may contain 90 per cent. of silver. The process generally employed is to smelt the slime so that the copper passes into the slag, which is then treated in the blast furnace, and a metal carrying 60 to 90 per cent. of silver results ; this is cast into ingots, which are passed on to the silver refinery.

The St. Louis Smelting and Refining Company and another large works in Pittsburg are using the Moebius process (English patent 16,554, 1884), in which silver is separated electrolytically from gold and other metals. The principle on which this process depends is, that when silver to be refined is made the anode in a weak nitric acid bath, the silver passes into solution as nitrate through the action of the electric current, and is redeposited in the metallic state upon a silver plate, which constitutes the cathode. The anodes are suspended from aluminium wire, which it is stated is not attacked by the nitric acid. With 70 vats in series, and a current of 180 amperes and 100 volts, 14 kilos of silver are obtained from each vat in 24 hours, giving a total of 980 kilos. The current density employed is 300 amperes per square metre.

* From *Dingler's Polytechnic Journal*, 1895, No. 296, pp. 284—288.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Prof. Perry has written to me objecting to Mr. Baily's rule about mean volts, as given in his letter on p. 762.

Of course it is very plain what kind of average was intended, as also it is very obvious that the mean voltage of an alternator is zero if alternate pulses are not rectified in sign ; but Prof. Perry considers that the more useful and appropriate sort of average for which to give a rule, would be the square root of mean square, being the quantity indicated by a voltmeter, and conveniently to be called *effective* volts ; and with this contention I am disposed to agree. In that case, as Prof. Perry says, the numerical factor needed to multiply the weber-amplitude and the frequency, to give the volts, would not be 4, but would depend on the form of the oscillation curve, and, for the case of a sine curve, would be $\pi\sqrt{2}$, which is about 4·44.

In stating the rule, such as it is (and no particular importance attaches to it—it was merely given casually as an illustration of the use of the term "weber-turns"), it would have been well to state that it was the *maximum* magnetic induction or the weber *amplitude* that was intended to be used in the technical phrase "weber-turns," and not the *mean* webers, about which there would be the same kind of ambiguity as there is about mean volts and averages in general.

I had hoped Prof. Perry would have written these simple remarks himself, but as he has not, I have endeavoured to give the gist of his criticisms, though he would doubtless have expressed them with more unction.

While on the subject, perhaps the following additional note to the Paper published in your issue for August 2nd, p. 450, may interest some of your readers :—"(23*a*) The expression weber-turns, to signify the product of the total field into the number of spires surrounding it, though at first sight not in precise correspondence with the phrase ampere-turns where the current circulates in the spiral instead of forming its core, is really accordant with it, because a spiral and its core are geometrically interchangeable."—Yours, &c.,

OLIVER J. LODGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Having seen Dr. Lodge's letter, I have to add that Mr. Baily's rule is not universally true for all kinds of periodic currents. If the periodic law of W (the weber-turns), however complicated it may be, is such that the time from maximum W to minimum W is half a period, and if it also happens that the maximum positive W is equal to the maximum negative W, then the mean voltage during this particular half period is equal to the maximum W multiplied by four times the frequency.—Yours, &c.,

JOHN PERRY.

October 23, 1895.

THE MAGNETIC FORCE INSIDE ANY CLOSED CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : The slip made by Mr. Colard in the second formula he sent you is a very obvious one, and is due, I cannot help thinking, to the adoption of Prof. Minchin's notation. His first formula,

$$F = \Sigma \frac{\sin a}{p}, \quad . \; . \; . \; . \; . \; . \; . \quad \text{(i.)}$$

Digitized by Google

gives a simple expression for the magnetic force on a unit magnetic pole at a point in the plane of a closed polygon of wire carrying unit current. In this formula, a represents an angle of the polygon, and p the perpendicular from the point on the line joining the feet of the perpendiculars on the two sides containing the angle. From this theorem we have to pass on to the case of a plane closed curve. In this case sin a is ultimately equal to the circular measure of the angle between two consecutive tangents, and p is the perpendicular on the tangent to the *pedal curve*. If we took p to have its usual meaning—namely, the perpendicular from the point on the tangent to the curve—we should get the second formula given by Mr. Colard. His second theorem is therefore

$$F=\int\frac{d\theta'}{p'}, \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(ii.)}$$

where θ' is the angle the radius vector of the pedal curve makes with a fixed line, and p' is the perpendicular on the tangent to the pedal curve, the integral being taken round the curve. Hence we can calculate the magnetic force inside a closed plane curve merely by considering the pedal curve.

For example, the pedal curve of a parabola with respect to its focus is the tangent at its vertex. In this case, $p'=$ constant $=a$; the magnetic force at the focus due to unit current in the parabolic wire

$$=\int_{-\frac{\pi}{2}}^{+\frac{\pi}{2}}\frac{d\theta'}{a}=\frac{\pi}{a}.$$

The formula (ii.) easily leads to many other theorems. For example, we can prove that in any closed curve

$$F=\int\frac{r\,d\omega}{p^2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(iii.)}$$

where r is the radius vector, p the perpendicular on the tangent and ω the angle which p makes with a fixed line.

The formula (ii.) seems worth trying in a good many cases, and our thanks are due to Mr. Colard for suggesting this method.—Yours, &c., A. RUSSELL.

Faraday House, Charing Cross-road.

ALTERNATE-CURRENT WAVE FORM DELINEATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would be a pity if M. Blondel's claim to priority over Messrs. Barr, Burnie and Rodgers' alternating wave tracer, and their half acknowledgment of the claim, were to draw attention from the essential novelty of their contrivance, which confers on it its chief value. The "new element" is not only the "mirror actuated by a cam," but the automatic movement of the contact brush so as to practically produce a wave of shorter period. M. Blondel moves a drum by clock-work. The other instrument shows the wave form on a screen at once.—Yours, &c., W. M. HICKS.

Dunheved, Endcliffe-crescent, Sheffield,
October 20, 1895.

SHAPE OF E.M.F. CURVE AND IRON LOSSES OF TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me to offer a few criticisms on Mr. C. P. Feldmann's article on the above subject appearing in your last week's issue?

Reference is made to the method of tracing the idle current of a transformer, and the method is ascribed to a Mr. A. Hill. On looking up the Index to Vol. XXXIV. of *The Electrician*, I failed to discover any contribution by a gentleman of that name, but found a series of articles on "Principles of Transformer Design," by Mr. A. Still. May I recommend Mr. Feldmann to consult Vol. XXVI. of *The Electrician*, where he will find, in a series of articles by Mr. S. Evershed ("The Magnetic Circuit of Transformers: Closed *versus* Open"), a very complete account of how to draw the idle current curve of a transformer, including the component required to balance eddy currents in the core.

The whole of Mr. Feldmann's article is marred by a blunder which is hardly credible in a writer of his reputation. An examination of the curves, along with the explanation given in the text, reveals the astounding fact that he proceeds to derive the curves of magnetic induction (*see* Figs. 5 and 6) from those of the primary E.M.F. (Figs. 1 and 2) by *differentiating* (instead of integrating) the latter! He then (correctly enough) differentiates the magnetic induction curves and obtains the curves of secondary E.M.F. Hence comes about the wonderful result that a transformer, whose primary E.M.F. is represented by the curve in Fig. 1, yields a secondary E.M.F. curve of the shape shown in Fig. 7!

It is obvious, from the above remarks, that Mr. Feldmann's article would have to be entirely re-written to be of any value.
—Yours, &c., ALFRED HAY.

University College, Nottingham,
October 21, 1895.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s. The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions can now be sent in.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with man original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper. price 6d.

A SHEET TABLE giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick aper, price 6d.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

Digitized by Google

Tenders Invited.—*Extension of Time.*—The Municipal Authorities of Tongres have extended the time for sending in tenders for the electric lighting of the town until November 8th. Tenders to the Conseil Municipale, Hotel de Ville, Tongres, Belgium.

——— The Electric Lighting Committee of the Bedford Urban Sanitary Authority require tenders for the supply and delivery of a surface condenser and air pump and of a centrifugal pump with engine. Tenders by November 1st to the Clerk (Mr. T. S. Porter), Town Hall, Bedford.

——— The Markets Committee of the Manchester Corporation invite tenders for the supply of two duplicate sets of vertical compound-condensing engines at the Foreign Animals Wharf, Mode Wheel. Tenders to the town clerk (Mr. W. H. Talbot) by November 5th.

Electric Lighting Schemes Invited.—The Battersea Vestry offer premiums of £50, £30 and £15 for the best three schemes, reports, designs and estimates for a system of electric lighting for the parish of Battersea. Schemes must be delivered to Mr. W. Marcus Wilkins, the Vestry Clerk, before 12 o'clock (noon) on Thursday, December 12th next.

Tenders Accepted.—The Manchester Corporation have accepted the tender of Messrs. Bolton and Sons for the supply of 15 tons of copper strip for their electricity works.

——— The Metropolitan Asylums Board have accepted the tender of Messrs. Muirhead and Co. for fitting up additional telephones at the new blocks of the Gore Farm Hospital at £72, and, subject to the sanction of the Local Government Board, the tender of the Callender Company for supplying and laying two new electric light cables at the hospital ships, at a sum of £125, has been accepted.

——— The Richmond (Surrey) Town Council have received the following tenders for an extension of the fire alarm service to Kew and Petersham :—

	£	s.	d.
Callender Company (for cables only) (*accepted*)	£165	6	0
Newland and Co.	371	0	0
Harrison, Coles and Co.	317	5	0
Consolidated Telephone Company	299	10	0
Julius Sax and Co.	250	0	0
F. E. Stuart (for instruments only)	46	7	6

(All of London.)

——— The Madras Railway Company have accepted the tender of the Brush Company for the supply of the necessary plant and apparatus for lighting the Arkonam Railway Station by electricity.

——— The tender of Messrs. F. A. Glover and Co., of Queen Victoria-street, E.C., has been accepted for wiring and fitting up the Cripplegate Institute for the electric light. The tender does not include electroliers, fancy fittings, or portable lights. The total number of lights will be 311, and the amount of the tender is £369. 11s.

Tenders Received.—The Newport Corporation have received 11 tenders for wiring the Provision Market and Public Baths for the electric light. The borough engineer's estimate for the work was £800. The following is the list of tenders sent in :—

	£	s.	d.
Sax (J.) and Co. (London)	£1,211	15	0
Binko (H.) and Co. (London)	1,200	0	0
Walker (S. F.) and Co. (Cardiff)	1,137	0	0
Fowler, Lancaster and Co. (Birmingham)	1,024	1	7
Maddren (T.) and Co. (Cardiff)	940	0	0
Bennett and Druce (Preston)	844	0	0
Baker and Co. (Newport)	829	0	0
Pettit and Hards (London)	719	0	0
Electrical Installation Company (London)	699	12	0
Arnold and Co. (Newport)	665	7	6
Alger and Sons (Newport)	630	10	0

Sales by Auction.—In reference to the announcement in our last issue of the sale by public auction of the works and plant of Poole and White, Limited (in liquidation), the auctioneers, Messrs. Wheatley Kirk, Price and Goulty, 49, Queen Victoria-street, E.C., and Albert-chambers, Albert-square, Manchester, notify us that the sale has been postponed *pro tem.*

Sale by Auction.—Messrs. Percy Huddleston and Co. will sell by public auction on Tuesday next, the 29th inst., at the Newton Heath Cable Works, Newton Heath, Manchester, some important plant and machinery, loose tools and utensils of an electric cable and wire works. The sale is announced to commence at 11 for 12 o'clock prompt, and catalogues may be had on application to the auctioneers, 72, Finsbury-pavement, London, E.C., or 20, Chapel-walks, Liverpool. Further particulars appear in our advertisement columns.

Dissolutions of Partnership.—The partnership business of electric wire manufacturers hitherto carried on by Messrs. John, Frank and Riley Patchett, under the styles of Patchett Brothers and the Northern Electric Wire Company, has been dissolved. Debts by Messrs. F. and R. Patchett, who continue the business.

——— Messrs. T. M. Heywood and P. R. Fergus, who have hitherto carried on business as electricians at Mount Stuart-square, Cardiff, under the style of Fergus and Co., have dissolved partnership. Debts by Mr. T. M. Heywood, who continues.

Appointment.—Mr. J. T. Dunn, D.Sc., has been appointed principal of the Northern Polytechnic Institute, Holloway, N. Dr. Dunn was until recently principal of the Plymouth Municipal Technical School.

Liquidations.—It was resolved on September 21st that the St. Martin's Electrical and Manufacturing Company (Limited) be wound up voluntarily. This resolution was confirmed on Oct. 10th, when Messrs. T. D. Dundas and C. Hancock were appointed liquidators.

——— Notice is given that creditors of Baird, Thompson and Co., Limited (in liquidation), must send in particulars of their claims to the liquidator, Mr. Isaac Coop (Davies, Tait and Co.), 46, Queen Victoria-street, London, E.C., on or before December 3rd next.

——— Creditors of the Hope Jones Electric Organ Company must send in particulars of their claims to the liquidator (Mr. R. S. Blease, C.A.), Fenwick-street, Liverpool, on or before December 14th next.

——— A meeting will be held at 26, Waterloo-street, Birmingham, on November 24th next, for the purpose of receiving an account of the winding-up of Armstrong's Glass Company (Limited).

Removals.—Mr. T. Harding Churton has removed his works and stores from Park Cross-street to larger and more convenient premises at 36, Great Wilson street; but all communications should be addressed to the offices, 5, South-parade, Leeds.

Russell and Co.—We are requested by Earl Russell to announce that, in consequence of the pressure on his time entailed by being a member of the London County Council, he has been compelled to relinquish the business of electrical contractor hitherto carried on by him under the style of Russell and Co., at 11, Queen Victoria-street.

Consolidated Telephone Construction and Manufacturing Company (Limited).—This Company announce that, owing to the expiry of the lease of their present works at the end of the current year, they recently purchased the freehold of the Overstone works, Coventry, together with a large plot of adjoining land, so as to give plenty of room for extension of business. The offices of the Company will remain in London, and due notice of any change in their location will be given. It is also stated that the services of the principals and most of the present staff have been retained, thus ensuring a continuance of the excellent workmanship for which this Company is justly noted.

Catalogue.—A copy of the new price list of "Brockie-Pell" arc lamps has been sent to us, and we note that these lamps have recently been considerably reduced in price. Messrs. Johnson and Phillips, who are the makers of the Brockie-Pell lamps, are to be congratulated upon the success which this lamp has met with, and on the general style and convenient arrangement of the catalogue.

College Calendar.—We have received a copy of the 1895-96 Calendar of the University College of North Wales. Very full particulars of the various classes and lectures are given.

Aberdeen.—The installation of the electric light in the extended buildings at Marischal College is now complete. The work has been carried out by Messrs. Shirras, Laing and Co., and about 730 lamps are employed.

Alleged Delay in the Transmission of Telegraph Messages between Paris and London.—In reply to a complaint as to the time taken in the transmission of telegraphic messages between Paris and London, the following letter from Mr. G. von Chauvin (representative in England of the Western Union Telegraph Company) appeared in *The Times* of the 18th inst. :—

"252, Gresham-house, Old Broad-street, London, E.C., Oct. 17th.

"Sir: In your issue of to-day I notice a letter signed 'Arbitrage' complaining of delay on telegraphic messages between Paris and London, and contrasting it with that experienced on messages to New York. The remedy suggested is an increase of the number of lines, and no doubt correctly, as the manner of working the wires, at all events on this side of the Channel, is not likely to be the cause of the delay. It is no doubt desirable that a greater number of telegraphic connections with the Continent should be provided, as the delay on messages exchanged between this country and the Continent is not only in itself a source of inconvenience to the public, but drives a considerable amount of the great international traffic which would otherwise pass over the English lines on to cables starting from Continental countries. A mere multiplication of existing facilities would not, however, it seems to me, entirely meet the case. During the stormy periods of the year a partial or entire breakdown in the telegraph lines leading to the coast is of more or less frequent occurrence, and the telegraphic communication now with one, now with another, foreign country is either greatly delayed or for a time entirely suspended. The remedy would be the establishment of underground lines serving, to begin with at least, the main routes of international communication, and avoiding the possibility of a severance of communication between the large English centres and the coast stations where the submarine cables terminate. Underground lines have for a long time been successfully worked in Germany. Their first cost is considerable, but the cost of maintenance is small, and by laying a

Digitized by Google

number of wires at once the cost per line of communication can be much reduced. But it would seem to me that the important point to be considered is the immunity from interruption. A total interruption between this country and the countries served, say, for instance, by the Eastern Company's system, might under easily-conceivable circumstances cost this country more money than would suffice for the establishment of an underground line from London to the Eastern Company's terminus, which would not only guarantee an unbroken continuity of service in times of need, but would be a boon at all times. From a long experience of the manner in which the telegraph department of this country is worked, I feel convinced that those responsible for its conduct are only too glad to take up and carry out every improvement, provided the necessary funds be allowed by those who have their keeping. I venture to suggest, therefore, that an expression of public opinion that a safer and more reliable means of telegraphic communication with the coast than that afforded by overhead lines should be established would produce advantageous results.—Yours, &c., "G. VON CHAUVIN."

ASSOCIATION OF MUNICIPAL CORPORATIONS.—The general meeting of this Association was held at the Westminster Palace Hotel on Friday last, Sir Albert K. Rollit, M.P., presiding. The Town Clerk of Southport (Mr. J. D. Williams) moved "That a request be addressed to the Board of Trade to promote a Bill in Parliament for the purpose of amending Section 9 of the Electric Lighting Act (1882) so as to provide that the annual statement of accounts should be made up to such date as the Council, with the approval of the Board of Trade, might from time to time appoint." The resolution was seconded and duly passed.

BANGOR (IRELAND).—At the last meeting of the District Council it was decided to make inquiries as to the advisability of applying for a Provisional Electric Lighting Order.

BEXHILL (SURREY).—The Urban District Council have been approached by the promoters of a syndicate for lighting the district electrically, and an application for the Council's consent to a Provisional Order has been referred to the Highways Committee.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY.—The Public Works Committee of the Birmingham Corporation have decided to recommend that this Company be allowed to introduce the overhead system of electric traction on their Nechells route.

BOLTON.—At the last meeting of the Gas and Electricity Committee it was decided to recommend the Town Council to adopt the Brighton method of charging for electric current. At the same sitting the Chairman of the Committee (Alderman Miles) and Mr. J. H. Rider were deputed to attend the forthcoming conference on the revised regulations of the Board of Trade as to the supply of electricity.

BRANDON AND BYSHOTTLES (DURHAM).—A special meeting of the District Council was recently held for the purpose of considering an estimate submitted by the Corlett Electrical Engineering Company, of Newcastle, for the lighting of the district by electricity. The Company offer to put down plant capable of maintaining 50 32 c.p. lamps for £480. The question of the cost of lighting the various wards in the district was discussed at great length, and various figures as to the cost, &c., were given by the Chairman. It was conceded that, on the basis of these figures it would be cheaper for the Council to adopt a system of electric lighting than gas. One member (Mr. Barnes) said that he was hitherto strongly in favour of gas lighting, but after the figures which had been read by the Chairman he could not oppose the proposal to light the district electrically. A resolution that the principal streets in the district be lighted by electricity, subject to satisfactory estimates as to cost being obtained, was unanimously carried. The Council intend to apply for a Provisional Order.

BRISTOL TRAMWAYS COMPANY.—The returns for the first complete week's working of the electric tramways prove the popularity of the line and the anxiety of the inhabitants of the city to test the advantages of electric traction. During the week no less than 92,516 passengers were carried.

BULUWAYO (SOUTH AFRICA).—The Buluwayo Waterworks Company are making rapid progress with their electric lighting scheme. It is stated that all the generating plant has been shipped, and that before many months have elapsed the installation of the electric light at Buluwayo will be an accomplished fact. It will be remembered that until two years ago Buluwayo was the home of Lobengula. Such is the march of events!

CARDIFF.—The Corporation have applied for sanction to borrow an additional sum of £12,882 for electric lighting purposes, and a Local Government Board inquiry will shortly be held in connection with the application.

CENTRAL LONDON RAILWAY COMPANY (LIMITED).—At the sitting of the Commissioners of Sewers on Tuesday, notice was received from this Company of their intention to sink a shaft for the purpose of investigating the state of the foundations of the Bank of England before starting work on the proposed subways opposite the Mansion House.

COSELEY (STAFFS.).—At the meeting of the District Council on Tuesday last a long debate arose on the question of the lighting of the streets. A proposal to canvass the ratepayers to ascertain whether the majority were in favour of the introduction of the electric light was rejected, and eventually the Council decided to continue the present system of gas lighting.

DAMAGES FOR AN ELECTRIC SHOCK.—In the Bloomsbury County Court last week an action was brought by a workman named Arnold against Harrod's Stores (Limited) for damages for personal injuries. The plaintiff, who was engaged by the defendants in some work on a building at Brompton, received a shock from an electric wire, and he alleged that his hand was so badly burnt he was unable to work for nearly five weeks. He contended that the accident was attributable to the defendants' negligence, as their engineer (Mr. Peters) should have informed him that certain wires which he was handling were "alive." After evidence had been given by Mr. Peters, Mr. D. C. Bate and others on behalf of the defendants, His Honour (Judge Bacon) found for the plaintiff £10 damages and costs.

DEVONPORT.—At the meeting of the City Council last week the Highways and Streets Committee presented their report on the notices that had been given by the County of London and Brush Provincial Company and the Great Western Electric Light and Power Company of their intention to apply for Provisional Orders for Devonport. The report, which recommended the Council to oppose the applications and to keep the supply of electricity in their own hands, was adopted. The Committee were authorised to take the necessary steps to apply for a Provisional Order.

DOCKS LIGHTING.—The Mersey Dock Board have decided to erect some additional arc lamps on the Prince's landing stage for the convenience of steamers, and a sum of £500 is to be expended on electric lighting at the Canada Lock and Huskisson Docks.

DOUGLAS (ISLE OF MAN).—The Manx Legislative Council on Tuesday approved the bill authorising the construction of a new tramway system in Douglas by the Isle of Man Tramways Company, and an extension for a term of 21 years of the concession from the Douglas Town Commissioners to the Company of the present tramway skirting Douglas Bay.

DOVER.—The work of erecting the iron brackets across Snargate-street for the suspension of the arc lamps for lighting this very narrow thoroughfare has been commenced.

GLASGOW.—At the meeting of the Police Commissioners on Monday, the Watching and Lighting Committee reported that on the suggestion of Bailie Guthrie a Sub-committee had been appointed to consider and report on the question of the electric lighting of the city, and particularly on the kind of lamp to be used for such lighting. The City Electrical Engineer (Mr. W. Arnot) and the Inspector of Lighting are members of the Sub-committee.

GLOUCESTER.—A deputation from the Corporation visited Bristol last week for the purpose of inspecting the new electric tramways and the Corporation electricity station. The Gloucester Corporation are considering the advisability of applying for a Provisional Electric Lighting Order, and a proposal is also under consideration for introducing a system of electric traction on the Gloucester tramways, the current being supplied to the Company by the Corporation.

HAMPSTEAD (LONDON, N.W.).—At the last meeting of the Vestry, on the recommendation of the Lighting Committee, it was decided to lay an electric light main in Boundary-road at a cost of £156. It was also reported that the Committee had considered the question of lighting the High-road, Kilburn, and they recommended that, on certain conditions, this thoroughfare be lighted by means of 24 arcs placed on rests in the middle of the road. By this arrangement the traffic would be regulated, and the illuminating power of the lamps would be greater than if the lamps were placed at the sides of the street. The cost of providing and erecting these arc lamps, rests, cable connections, &c., would be £1,009. 4s., and the annual up-keep of each lamp was estimated at £29. 13s. 6d. The Committee therefore recommended that the Willesden District Council be informed that the Vestry will light the street electrically, provided they agree to pay half the initial outlay and annual cost of maintenance. This proposal was, after a brief discussion, agreed to by the Hampstead Vestry. The Lighting Committee also reported that at the present time they were supplying current to an equivalent of 17,000 c.p. lamps to private consumers, and they had applications in hand for over 3,000 more.

HANLEY.—Mr. G. W. Willcocks, M.I.C.E., held a Local Government Board inquiry at Hanley, on the 16th inst., into the application of the Town Council for permission to borrow £20,000 for the purpose of extending the electric light works and mains. Mr. A. Challinor (the Town Clerk) stated that the assessable value of the borough was £182,238, and the outstanding debt amounted to £195,460, including £30,000 for electric lighting. There was no opposition to the application, and the proposed loan was to extend the buildings, boiler plant and switchboard required for the new alternator, and to extend the mains in different parts of the town. So far the Corporation had limited the supply of current to consumers within the compulsory area, but the demand was continually increasing, and was now so great that although the markets were wired and fitted

Digitized by Google

up for the electric light, it was not considered safe to connect them with the mains until further generating plant had been provided. The result of the first six months working (ended December 31st last) was that a profit of £31 was made after providing for working expenses, interest, and sinking fund. The Borough Engineer and Surveyor (Mr. Joseph Lobley, M.I.C.E.) and the Corporation electrical engineers presented a report, which was unanimously approved at a Council meeting on April 30th last. The report divided the work in connection with the proposed extensions into six sections, and the following is a summary of the recommendations:—(1) Extension of mains to Market, Bath, Hope, Clough, Charles, Trinity, Stafford, Tontine, Jasper, Bethesda and Broad-streets, Etruria, Regent, Stoke, Victoria, Avenue and Park-roads, Piccadilly, Pall Mall, Birch-terrace, Snow-hill and Park-avenue. These include high and low-pressure mains, and for a second circuit of 30 arc lamps. The estimate for these cables, including laying, is £5,508. (2) Extension of the buildings at the generating station (leaving room for an additional boiler, condenser and steam alternator when the same are required), two new boilers and appurtenances, 16 sub-stations, 20 transformers, 25 junction boxes, and 30 arc lamps and posts. The estimate for this list is £5,900. (3) Two Ferranti rectifiers for both the present circuit of 30 arc lamps and for the new circuit, the present arc dynamos and engines being retained as reserve; also 30 incandescent street lamps complete on new roads round the park, and 60 ditto in other parts of the town where mains are being laid. Extension of switchboard and excavations and railings at works. The estimated cost of this work is £1,242. (4) In consequence of the demand for energy within the compulsory area, considerable extensions have been made to the machinery, mains, sub-stations and transformers, amounting to £2,650, and to the buildings, furniture, excavating, drainage and formation of ground, amounting to £2,000; sundries, £200. Total, £4,850. (5) Provision for contingencies, £1,000, special regard being had to mains being laid to supply manufacturers with motive power. (6) Meters and switches provided on consumer's premises, £1,500, including £250 already expended. Mr. Lobley gave a detailed explanation of the purposes for which the loan was required, and Messrs. Cowell and Sutherland (the electrical engineers and joint managers of the electricity works) showed the increase in the number of lamps connected, which was now considerably above the capacity of their present generating plant—viz., an equivalent of 10,000 8 c p. lamps. After the termination of the inquiry the inspector visited the works, and proposed new lines of mains and arc lamps.

Illinois Central Railway Company.—This Company announces that it has decided to adopt a system of electric traction on its suburban lines. The work of electrically equipping the lines will shortly be commenced.

Islington (London, N.).—At their last meeting the Vestry resumed the consideration of the Electric Lighting Committee's report, which stated that a further sum of £25,000 would be required for the purpose of completing the electric light undertaking. The report was adversely criticised by several of the members, and the electrical engineer (Mr. A. Gay) attended and made a personal statement in support of the Committee's position, after which the report was agreed to. It is reported that the Vestry have already received applications for current equivalent to 9,237 8-c.p. lamps, and this is a fairly good proof that the Vestry's electric light undertaking is likely to be as decided a success as the schemes of the St. Pancras and Hampstead Vestries.

Kettering.—A proposal for lighting the principal streets of the town by electricity has been before the Town Council for some time, and the Lighting Committee are canvassing the ratepayers with the view of ascertaining the amount of local support likely to be given to the scheme. It is stated that the feeling in favour of the introduction of the electric light is decidedly on the increase.

Kingstown (Dublin).—At their last sitting the Town Commissioners decided to apply for a Provisional Order.

Lancaster.—At the meeting of the Town Council on Wednesday last the resignation of the borough electrician (Mr. A. S. Barnard) was formally received and accepted. It was suggested "that future appointments should be made for a term of years so as to avoid repeated changes in the officials." So far as we can understand no suggestion was made to increase the handsome salary attached to the office, viz., £120 per annum. If the Council considered this question they might possibly discover the cause of the "repeated changes in the officials."

Light Railway in Derbyshire.—The proposed construction of a light railway between Derby and Ashbourne is exciting much local interest. The suggested motive power is electricity, and two numerously-attended meetings in support of the scheme were held last week. In the first case a number of local landowners, farmers and tradesmen assembled at the Guildhall, Derby, on Friday last. The Chairman (Mr. C. E. Newton) said the matter deeply affected the town of Derby and the agricultural interests of the county. He appealed for subscriptions to meet the preliminary expenses for obtaining Parliamentary powers, which he said would be over £700. In the discussion which followed the various speakers favoured the principle of the scheme, and a resolution was passed expressing approval thereof, endorsing the steps taken by the local committee for furthering the project, and declaring the desirability of taking steps to obtain the necessary Parliamentary powers. The other meeting was held on Saturday at Ashbourne. Mr. A. C. Duncombe, who presided, explained the scheme at great length and heartily supported the proposal, as he said he was persuaded that the railway would prove of great value to the agricultural interests of the county. It was also stated that Sir H. Oakley (General Manager of the Great Northern Railway Company) had promised to assist the promoters of the scheme as far as possible; the light railway with its goods traffic would run into the yard of the Great Northern Company, where the goods could be easily and cheaply transferred. A resolution heartily approving of the scheme was also adopted at this meeting.

Llandudno.—The District Council have been requested to sanction the construction of an electric tramway in the town. It is proposed to use storage batteries.

Llandrindod Wells.—The District Council have received proposals from a Birmingham firm for the lighting of the district by electricity, and a special meeting of the Council is to be held to consider and discuss the matter.

Macroom (Cork).—A scheme for the lighting of this town by electricity is being prepared by a local syndicate. It is acknowledged that artificial lighting of some kind is absolutely necessary, and electric lighting ought to prove very much cheaper than any other form of illumination, especially as water power is available in the vicinity of the town.

Newcastle-on-Tyne.—The Improvement Committee have presented a report on the working of the tramways. The report was considered by the City Council at their meeting on Wednesday, and recommends the adoption of a cable system. The cost of the proposed scheme, including engine-houses, engines, track, and conduit, but exclusive of land for power station, is estimated at about £125,000. By an arrangement the lessees of the present tramways agree to work the cable system. The Corporation are to grant a new lease to the Company for 21 years, and the Company are to pay to the Corporation half-yearly rent at the rate of 6¼ per cent. per annum on the total cost of construction and equipment, and on so much of the debt on the portion of the existing tramways proposed to be cabled as will be unprovided for after giving credit for all material displaced. The lessees are also to pay to the Corporation interest at the rate of 3 per cent. per annum upon the cost of purchasing the site for the power station. The report was adversely criticised by several members, who urged the Corporation to follow the example of Leeds and adopt a system of electric traction. The further consideration of the matter was adjourned until Monday next.

Newington (London, S.E.).—The Vestry of St. Mary, Newington, have engaged Messrs. Kincaid, Waller and Manville to advise them on the question of the adoption of an electric lighting scheme.

Port Adelaide (South Australia).—From latest advices we learn that the Port Adelaide Corporation have decided to light the principal streets of the town by electricity, and the tender of the South Australian Electric Light and Motive Power Company for carrying out the scheme has been accepted.

Queenstown.—A special meeting of the Town Commissioners was held on Tuesday last to consider the best mode of lighting the town. The Commissioners have on many previous occasions discussed this question, and it is satisfactory to be able to record that they have at last made up their minds to apply for a Provisional Electric Lighting Order. 6s. 11d. a thousand for gas ought to be sufficient to induce any local authority to come to a similar decision. The Commissioners and the local gas company have been at loggerheads for a considerable time past over the price and quality of the gas supplied for the lighting of the streets, and though several applications for a reduction in the price had been made, the gas company resolutely declined to entertain any such proposal. The Commissioners have decided to erect four arc lamps, partly as an experiment and partly to demonstrate to the ratepayers the great advantages of the electric light.

Ramsgate.—The coastguard station on the cliffs at Ramsgate has been put in telephonic communication with the harbour, the object being to enable information of disasters on the Goodwins to be more speedily communicated to the Ramsgate tug and lifeboat.

Sunderland.—The report of the Highways Committee, presented at the last meeting of the Town Council, recommended that the electric light mains be extended to the St. John's Wesleyan Lecture Hall, Ashbrooke-road; that mains be purchased for laying along Vine-place, Homeside and Green-terrace, at a cost of £188, and that additional meters be purchased at a cost of £106. 11s. 6d. The report was duly approved.

Digitized by Google

St. George's (London, S.W.).—At the last meeting of the Vestry, Mr. Bromwich again raised the question of lighting the streets by electricity. He complained that they were 10 years behind the time in the matter, and he urged his fellow members to bestir themselves and to take the question into serious consideration. The Surveyor, in reply, stated that he was preparing a report on the subject at the instance of the Works Committee, and it would shortly be presented.

St. Pancras (London, N.W.).—At the last meeting the Vestry, several new applications for current were announced. Mr. Hodgson raised a debate on the action of the Electricity Committee in increasing the pressure at which electric current is supplied to new customers from 110 to 220 volts, but after some discussion it was decided to support the action of the Committee.

Swadlincote (Burton).—The Water and Lighting Committee of the District Council are considering a proposal for lighting the Stanton Ward by electricity.

Taunton.—The Electric Light Committee have applied to the Board of Trade for a further extension of one year to complete the work of laying underground mains and removing the overhead wires. They also require a further loan of £3,000 for electric lighting purposes, and the Finance Committee have been authorised to raise this amount.

Telegraphic Messages per Telephone.—The National Telephone Company announce that the charge of 1½d. per message hitherto made to their customers for sending telegrams to the Post Office by means of the telephone, has been abolished, and telegrams can now be transmitted and received without extra charge over and above that due to the Post Office. Before subscribers can use the telephone for this purpose the District Manager must be communicated with and a deposit left with the Company sufficient to cover the cost of telegrams likely to be sent during a month.

The Metric System.—It is stated that the Mexican Government have decided to adopt the metric system of weights and measures as from September 16, 1896.

The Provincial Telephone Service.—A conference took place in Bradford on Tuesday last between delegates from the various Chambers of Commerce in the West Riding of Yorkshire and representatives of the National Telephone Company, for the purpose of discussing and considering complaints against the present management of the telephones, and to urge for a reduction of the annual subscription. The chair was occupied by Mr. T. A. Duncan (President of the Bradford Chamber of Commerce), and representatives from the Bradford, Halifax, Huddersfield, Heckmondwike, Birstall, Yeadon, Keighley, Ossett, Cleckheaton and Wakefield Chambers were also present. The National Company were represented by Alderman Franklin (a Director), Messrs. W. E. L. Gaine (General Manager), J. C. Chambers (provincial superintendent), and N. B. Sutcliffe (District Manager). Mr. Gaine went through the various complaints. He said that any arrangement to make one subscription cover the six areas into which the West Riding was divided would have to be done with the concurrence of the Government, and he understood they would be disinclined to amalgamate these areas. As to the question of providing their subscribers with pass cards and copies of the general directory free, he thought the existing charges were reasonable, but the Company would carefully consider any proposals for making the local lists more convenient and useful. The proposed extension of the time of conversation from three to five minutes was entirely in the hands of the Government, as was likewise the erection of additional trunk lines; by their agreement with the Post Office they were bound not to extend these trunk lines without the Postmaster-General's consent. He had gone carefully into the matter, and he was of opinion that in order to meet the present traffic additional trunk lines were required as follows:—From Bradford: Two to Huddersfield, two to Halifax, three to Dewsbury, two to Wakefield, and one to Harrogate. From Huddersfield: Two to Halifax, two to Leeds, and two to Dewsbury. From Halifax: Two to Leeds. From Leeds: Two to Dewsbury, four to Wakefield, and two to Harrogate. The question of the annual charge was next dealt with. Mr. Gaine alluded to the fact that subscriptions to Continental telephone exchanges were low as compared with the rates paid by the National Company's subscribers. This fact he attributed to the numerous obstacles to the development of the service that had been put in their way. He also adduced some figures in favour of this contention, and said that under the present conditions he could not hold out any hope of a reduction, but the Company would do all in their power to make the service efficient. A discussion followed, and eventually a motion was passed to the effect that a memorial be forwarded to the Postmaster-General urging (1) the necessity for additional trunk lines being provided without delay, and (2) that the six areas into which the West Riding district is divided should be combined into one area.

Weybridge.—At the last meeting of the District Council a draft of the proposed contract with the local gas company was submitted, and after several alterations had been made therein the further consideration of the matter was postponed. Some time ago the Council wrote to the Board of Trade asking if the Weybridge Provisional Order (1891) could be transferred to them instead of being revoked, and the Board have now replied to the effect that the only way to avoid the proposed revocation was by the purchase of the Weybridge Electricity Works by the Council. It was, therefore, decided to ascertain on what terms the Weybridge Electric Supply Company would transfer the Order to the Council.

Wimbledon (Surrey).—At the last meeting of the District Council it was stated that the Local Government Board would shortly hold an inquiry into the application of the Council to borrow money for an electric lighting scheme. The resolution recently passed by the Ratepayers' Association relative to the scheme was presented, and an application from the Association asking the Council to receive a deputation of their members on the subject was refused.

Workhouse Lighting.—Some time ago a Bedford firm wrote to the Great Berkhampsted Board of Guardians offering to instal the electric light at their workhouse. The proposal was discussed at the last meeting of the Board, but in the absence of figures as to cost, &c., the consideration of the matter was postponed.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

October 10, 1895.

19,002. H. Brecknell. Bristol. An improved wheel trolley for single-wire system of electric traction.

19,027. W. L. Wise. London. Improvements in electric metering apparatus. (W. S. Barstow, United States)

19,067. F. Warren. London. Improvements in electric signalling apparatus.

October 11, 1895.

19,104. F. E. Buxton. Manchester. An improved method of making and applying electric rail-bonds. [Date applied for under Patents, &c., Act, 1883, Sec. 103, April 15, 1895, being date of application in United States.]*

19,130. P. C. D. Castle. Liverpool. New or improved chemical substance and the application thereof to industrial purposes, such as rubber, gutta-percha, or celluloid substitutes, insulations of electrical conductors, coverings for ships' bottoms, or wall and floor coverings.

October 12, 1895.

19,177. H. O. Johnson. London. New or improved electric lantern for velocipedes.

19,199. A. G. New and A. J. Mayne. London. Improvements in dynamos.

19,204. J. R. Gibson. London. Improvements relating to electric signalling in open circuits.*

October 14, 1895.

19,245. R. Wood. London. Improvements in dynamo-electric generators and motors.

19,256. F. J. Beaumont and F. Hallows. London. An improved electricity meter for registering the amount of current consumed on direct or alternating polyphase, triphase, or quadruplephase circuits.

19,260. J. E. Horea and A. Olteanu. London. Improved electrical apparatus for preventing the collision of railway trains.

19,272. E. R. Kesterton. London. Improvements in or relating to the steering of electric or steam carriages, cycles, bath chairs, or other like vehicles.

October 15, 1895.

19,275. R. J. Bott. London Improvements in electric incandescent glow lamps.

19,304. W. L. Wise. London. Improvements in phosphorescent electric lighting. (The Moore Electrical Company, United States.)*

19,317. J. la Burt. London. Electric railways.

19,318. J. G. Smith and R. G. Vassar. London. Improvements in combined telephone and signalling systems.*

19,337. W. P. Thompson. Liverpool. An improved means for connecting the filament in incandescent lamps with the source of current. (The Phönix Süddeutsche Glühlampenfabrik Gesellschaft, Germany.)

16,008. DILLBERG and RABBIDGE. Telephonic instrument.

COMPANIES' MEETINGS AND REPORTS.

Froggatt's Electric Lighting Company (Limited).

An extraordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Monday (Mr. A. de Murrieta in the chair) to consider two resolutions: (1), as to the appointment of a committee of the shareholders to confer with the Directors on the conduct of the business in the past, and also as to the future management of the business and the steps to be taken to promote the success of the Company, and (2), empowering the Committee, at its discretion, to make a report to the shareholders.

The SECRETARY (Mr. A. S. Hiley) having read the notice convening the meeting,

The CHAIRMAN, in proposing the first resolution, stated that, in accordance with an undertaking given by the Board, the present meeting had been called for appointing a committee to confer with the Directors. The Board had no names prepared to act as the committee, preferring to leave its election to the shareholders' initiative. He then invited the nomination of candidates.

Mr. KEEBLE wished to know the necessity for the proposed committee, the proper committee for managing the Company's affairs being, he contended, the Directors.

Mr. WILDEY said he did not think it was necessary to discuss the point just raised. The report showed a profit for twelve months of £239. He saw the light in omnibuses and they heard remarks about it, and the question was—Where had all the money gone to? He thought that there was every reason why they should have a committee, and he would second the resolution.

Mr. KEEBLE replied that the Chairman explained at their recent meeting the causes why a dividend had not been paid, and made a statement, upon which the shareholders adopted the report. The Chairman also mentioned the grounds on which he had reason to suppose that the business would be successful in the future. He hoped a committee would not be appointed unless they made a report to the shareholders; but, in his opinion, the appointment of a committee was useless, and he regarded it as the beginning of proceedings which might wreck the Company. He proposed an amendment providing that, instead of having any discretion vested in them in such a matter, the committee should report to the shareholders the result of their conference with the Directors.

Mr. HAYWARD seconded the amendment, and proposed an addition to it (which was accepted by Mr. Keeble), that the committee should present their report to the shareholders within 28 days.

The CHAIRMAN said he thought that if they limited the period to 28 days the Directors would oppose the amendment, but they did not otherwise object to the amendment. In leaving it to the discretion of the Committee to report or not to the shareholders the result of their conference with the Board, it had been thought that certain matters might be privately discussed the publication of which might be detrimental to the interests of the Company. He submitted the amendment, and declared it lost, and afterwards put the original motion, which he declared carried.

Mr. Keeble and four other shareholders demanded a poll, and the Chairman said that the poll would be taken on the following day, and the meeting was adjourned to yesterday (Thursday) at four o'clock, for the declaration of the result.

At the meeting yesterday,

The CHAIRMAN read the result of the poll as follows: In favour of the resolution, 19,224 votes; against it, 11,578. He therefore declared the resolution carried.

Mr. CAPEL CURE then proposed the appointment of Mr. Stanhope (a former Director) and Mr. Curling Hunter as members of the committee.

Mr. KEEBLE proposed the appointment of Mr. Hayward.

The CHAIRMAN said the resolution he would propose was—

"*That Mr. Stanhope, Mr. Hunter and Mr. Hayward, being shareholders of the Company, be, and they are hereby appointed to act for the purposes specified in the preceding resolution.*"

Mr. C. DE MURRIETA seconded the motion.

Mr. KEEBLE moved an amendment to the effect that the Committee report the result of their conferences to a meeting to be called for that purpose.

The SOLICITOR stated that the amendment should have been proposed on the previous resolution.

The CHAIRMAN accordingly ruled the amendment out of order, and put the resolution, which he declared carried.

The proceedings then terminated.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The report of the Directors for the half-year ended June 30th last, to be submitted to the forty-fourth ordinary general meeting, which will be held at Winchester House, Old Broad-street, London, E.C., on Wednesday next, the 30th instant, at 2 o'clock, states:—

The gross receipts, including Government subsidies, have amounted during the period to £264,138. 10s. 5d., against £247,681. 2s. 4d. for the corresponding half-year of 1894. The working expenses, including £29,323. 19s. 7d. for cost of repairs to cables and expenses of ships, absorb £95,254. 14s., against £80,295. 3s. 10d. for the corresponding period of last year, leaving a balance of £168 883. 16s. 5d. From this is deducted £3,984. 3s. 2d. for income tax, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving £133,004. 13s. 3d. as the net profit for the half-year. Two quarterly interim dividends of 1¼ per cent. each, amounting to £62,500, have been paid for the half-year under review, leaving £70,504. 13s. 3d. to be carried forward.

The working of the Australasian tariff arrangement for the fourth year of guarantee, ended April 30th last, resulted in the guaranteed figure being slightly exceeded owing to the exceptionally heavy gold mining traffic that was exchanged with Australasia during the latter part of the year.

The maintenance ships have, as usual, been kept employed during the half-year under review on the various sections of the Company's cables, but owing to the cables being duplicated the traffic has in no instance been interrupted.

Brazilian Submarine Telegraph Company (Limited).

The following report of the Directors of this Company, for the half-year ended June 30 last, will be presented to the forty-fourth ordinary general meeting, to be held at 174, Winchester House, Old Broad-street, E.C., on Wednesday next, the 30th inst., at 12 o'clock noon:—

The revenue for the period amounted to £108,205. 14s. 5d., and the working expenses to £21,129. 4s. 11d. After providing £3,200 for debenture interest and sinking fund, and £1,790. 1s. for income tax, there remains a balance of £82,086. 8s. 6d.; to this is added the sum of £4,324. 0s. 9d. brought forward from the preceding half-year, making a total of £86,410. 9s. 3d. A quarterly interim dividend, amounting to £19,500, has been paid, and £30,000 transferred to the reserve fund. The Directors now recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share (both free of income tax), which together will amount to £32,500, leaving a balance of £4,410. 9s. 3d. to be carried forward. The dividend and bonus are payable on the 31st inst.

The receipts for the half-year include the sum of £1,500 dividend to December 31st last on the Company's shares in the African Direct Telegraph Company (Limited). The various sections of the Company's lines are in good working order.

The retiring Directors are Lord Sackville A. Cecil and the Duke de Loulé, who, being eligible, offer themselves for re-election, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Gane, Jackson and Jefferys.

Monte Video Telephone Company (Limited).

The following is the report of the Directors of this Company for the year ended July 31, 1895, which will be presented to the shareholders at the annual general meeting to be held at Winchester House, Old Broad-street, London, E.C., at 12 o'clock noon, on Thursday next, the 31st inst.:—

The statement of accounts for the period shows a net profit of £7,232. 18s. 5d. This amount, added to the balance of £577. 18s. 8d. brought forward from last year, leaves a sum of £7,810. 17s. 1d. available, after providing for working expenses in Monte Video and London and for loss in exchange, and after writing off amounts for bad debts and depreciation of office furniture. The working expenses in Monte Video have been somewhat heavier than usual owing to a succession of severe storms which occurred during the early part of the year, when much damage was done to the plant. At the cost of revenue, however, the property has been maintained in good working order.

After placing £1,000 to reserve account and £500 to the depreciation fund, the Directors recommend the payment of a dividend of 4 per cent. on the Preference shares absorbing £5,600, and leaving the sum of £710. 17s. 1d. to be carried forward to next year.

In accordance with the Articles of Association, Mr. Charles H. Sanford retires from the Board, and, being eligible, offers himself for re-election, as do the auditors, Messrs. Gérard Van de Linde and Son.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRITISH ELECTRICAL MANUFACTURING AND ENGINEERING COMPANY (LIMITED).—This Company was registered on October 18th, with a capital of £20,000, in £5 shares, to manufacture, erect, use and deal in telephones, telegraphs, electric bells and all other electrical apparatus; to carry on the business of manufacturers of and dealers in electrical generators, motors, accumulators, electrical elevators, carbons, steam and other engines, iron, copper and other wires, electrical conductors and other apparatus used in connection with the generation, accumulation, supply or utilisation of electricity. The subscribers, with one share each, are: P. Capps, H. D. Monk, F. C. Smith, J. Hill, J. Davis, F. A. Braithwaite and C. A. Cox. One Director is to be nominated by Messrs. Laing, Wharton and Down, and he is to remain in office so long as they are interested in the Company.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS (LIMITED).—This Company was registered on October 21st with a capital of £50,000, in 30,000 Seven per Cent. Preference shares and 20,000 Ordinary shares of £1 each, to enter into an agreement with the General Traction Company (Limited), to acquire, equip and work with electric, mechanical, or other motive power, carry on and maintain railways, tramways, roads and auxiliary railways in the Isle of Man, or elsewhere in the United Kingdom, and to carry on the business of electrical and mechanical engineers, electricians, and suppliers of electric light. The subscribers, with one share each, are: W. S. Graff Baker (electrical engineer), W. P. J. Fawcus (engineer), G. W. Lowcock (electrical engineer), J. H. Beech, H. Taffs (electrician), A. E. Tanner and T. S. Turnbull.

HYDRAULIC POWER IMPROVEMENTS COMPANY (LIMITED).—This Company was registered on October 17th, with a capital of £10,000, in £1 shares, to enter into an agreement with Jean Molas, civil engineer, High-road, Tottenham, London, N., for the acquisition of certain patents, and to carry on business as mining and mechanical engineers, concessionaires, makers of hydraulic lifts, &c.

SIEMENS BROS. AND COMPANY (LIMITED).—The annual return to August 27th has been filed. The capital is £500,000, in £100 shares, all of which have been taken up. Calls amounting to £85 per share have been paid.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return to August 29th has been filed. The nominal capital amounts to £500,000, in 49,900 £10 shares and 1,000 £1 shares; 23,719 of the former class have been taken up, and of these all but four have been issued as fully paid.

THAMES VALLEY LAUNCH COMPANY (LIMITED).—An agreement, dated the 27th inst., has been made by this Company with Mr. W. R. Edwards, electrical engineer, of Weybridge, for the sale of the business of launch and boat builder and owner, and electrical engineer carried on by the vendor, for £1,500, payable by the allotment of 300 fully-paid shares of £5 each.

VEALE AND COMPANY (LIMITED).—The annual return of this Company has been filed. The nominal capital is £10,000, in £1 shares, and 4,904 of these have been taken up: 3,839 have been issued as fully paid, and the full amount has been called and paid on the remaining 1,065 shares.

WESTRALIAN ELECTRIC LIGHTING AND SUPPLY COMPANY (LIMITED).—This Company has entered into an agreement with Westralia (Limited) for the purchase of a certain exclusive concession to supply electricity for various purposes, granted by the Municipal Council of Coolgardie, Western Australia, for £45,000, of which £40,000 is to be satisfied by the allotment of 40,000 fully-paid shares of £1 each.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 31 $\frac{1}{16}$d. per oz. (Oct. 24th). Consols (2¾ per cent.) 107⅝–107 $\frac{7}{16}$ for money, 107 $\frac{5}{16}$—107 $\frac{7}{16}$ for account; 2½ per cent. 105½—106¾ (Oct. 24th). Stock Exchange Settling Days: Consols, Nov. 6th; Stocks and Shares Continuation Day, Oct. 28th; Ticket Day, Oct. 29th; Pay Day, Oct. 30th.

AMAZON TELEGRAPH COMPANY (LIMITED).—The first ordinary general meeting of this Company will be held at Winchester House, Old Broad-street, London, E.C., on Thursday next, the 31st inst., at 12 o'clock.

CASTNER-KELLNER ALKALI COMPANY (LIMITED).—This Company is inviting subscriptions for 200,000 £1 shares, payable 2s. 6d. on application, 2s. 6d. on allotment, 2s. 6d. on January 1st next, and the balance as may be required. The capital of the Company is £300,000, in £1 shares, and the prospectus states that, in view of an arrangement made between the Aluminium Company (London), owners of the Castner patents, and MM. Solvay et Cie. (Brussels), owners of the Kellner patents (except for Austria), the Company has been formed for the purpose of manufacturing caustic soda and bleaching powder by electrolysis under the combined patents of Mr. H. Y. Castner and Dr. C. Kellner in Great Britain and Ireland and the British colonies, except Canada. New works are to be erected by the Company at Runcorn, where, it is stated, the processes have been worked experimentally with satisfactory results for some time past. The vendors take the remaining 100,000 shares in part payment of the purchase-money, and the Directors of the Company are: Messrs. F. Burton, Hamilton Y. Castner (Director of the Aluminium Company), F. Hardcastle, Dr. C. Kellner, William Mather (Mather and Platt, Limited) and Sir H. E. Roscoe. The offices are 13, Abchurch-lane, E.C., and the secretary (*pro tem.*) is Mr. G. H. Clarkson. The lists opened yesterday (Thursday) and close to-day.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended October 20th were £927, against £932 in the corresponding week of 1894, a decrease of £5. The total receipts for the half-year amount to £13,701, against £13,863 for the corresponding period of 1894, a decrease of £162.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The revenue return of this Company for the quarter ended September, 1895, is as follows: Sale of current for public lighting, £3,182, against £3,141 in the corresponding quarter last year; private lighting, &c., £11,600, as compared with £7,676; estimated revenue from other sources, £400, against £416; total £15,182, as compared with £11,233, or an increase of £3,949. There was an equivalent of 170,827 8 c.p. lamps connected up to the Company's mains on September 30th, an increase of 11,577 8 c.p. lamps, against 13,724 8 c.p. lamps in the corresponding quarter of 1894.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS COMPANY (LIMITED).—During the week this Company, which has been formed for the purpose of acquiring an exclusive concession for the operation of an electric tramway (on the overhead system) upon the Douglas Head Marine Drive, invited applications for 20,000 Seven per Cent. Preference and 10,000 Ordinary shares of £1 each, payable 5s. on application, 5s. on allotment, and the balance on December 1st next. The nominal capital of the Company is £50,000, divided into 30,000 Preference and 20,000 Ordinary shares of £1 each. The concession is for a term of 10 years, and at the expiration of this period the Douglas Head Marine Drive (Limited) (the grantors of the concession) have the option of either purchasing the undertaking on certain conditions stated in the prospectus, or of renewing the concession for a further period of 21 years upon agreed terms. The Company has entered into a contract with the General Traction Company, Limited (the vendors) for the acquisition of the tramways in working order, with certain specified plant, rolling stock, buildings, &c., and for the assignment of the concession and all the rights and privileges thereunder. The estimated cost of the construction and equipment of the first 2½ miles of the tramway is £29,000, payable £25,000 in cash and £4,000 in Ordinary shares or cash. The consulting engineers (Messrs. Kincaid, Waller and Manville) have reported favourably to the Company on the scheme, and the prospectus states that it has been estimated there will be sufficient profit to pay a dividend of 11 per cent. per annum on the Ordinary shares of the Company, besides paying the interest on the £20,000 Preference shares. The Directors of the Company are Messrs. J. S. Goldie-Taubman, J.P. (Speaker of the House of Keys), who will act as Chairman, W. Turton, W. P. J. Fawcus, W. S. Graff Baker and G. W. Lowcock. The offices of the Company are at 71, King-street, Manchester, and 11, Athol-street, Douglas, Isle of Man, and the secretary is Mr. F. R. Rowe. The lists opened on Saturday and closed yesterday Thursday.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on November 1st of interest for the half-year ended October 31st on their Four per Cent. Mortgage Debenture Stock. The transfer books of the Company will be closed from the 27th inst. to November 1st, both days inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on November 1st next of interest on their Four per Cent. Mauritius Subsidy Debentures. The transfer books will be closed from the 27th inst. to the 1st proximo, inclusive.

LEIPZIG ELECTRIC TRAMWAY COMPANY.—This Company, which has been formed by the Allgemeine Elektricitäts Gesellschaft and some German banks, recently invited subscriptions for £162,500 (one half of the nominal capital of the Company) at 138 per cent., and according to a Munich paper applications for £614,000 were received. There will be about 15 miles of tram line with a total length of track of about 27 miles. For the construction and equipment of the tramway the Allgemeine Elektricitäts Gesellschaft will receive £291,800, and, according to concession, the line must be opened in 1896.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 20th inst. amounted to £1,104. The amount for the corresponding week last year was £888; increase, £216.

SOCIETE ANONYME ELECTRICITE ET HYDRAULIQUE.—The Directors of this Company have declared a dividend at the rate of 5 per cent. per annum for the year 1894-95.

SOCIETE ANONYME L'ELECTRO-HYDRAULIQUE.—A Company bearing this title, and having a capital of £10,000, has been formed in Brussels for carrying on an electro-chemical and metallurgical business.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Tuesday next, the 29th inst., a special settling in 143,971 shares (5s. paid) of the Smelting Company of Australia (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—At a meeting of the Board of this Company held yesterday (Thursday) it was decided that, after placing £7,876 to the Debenture Redemption Fund and £5,000 to the reserve fund, the Directors would (subject to audit) recommend at the forthcoming meeting a dividend at the rate of £2. 10s. per cent. per annum, free of income-tax, for the six months ended June 30 last, as against a dividend at the rate of £2 per cent. per annum for the corresponding period of 1894, carrying forward £5,803. The dividend will be payable as follows—3s. 9d. per share to the Ordinary shares and 3s. 9d. per share to the Preferred Ordinary shares.——The Company's traffic receipts for the week ended October 18th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,009.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended October 15th are £2,094, as compared with £1,901 in the corresponding period of 1894.
